PROVINCIAL ILLUMINATIONS.

The provincial electricity supply authorities were exceptionally busy during the Coronation and seem to have lost no opportunity in getting a good advertisement for electric lighting in general and for decorative illumination in particular. Mr. W. Bache, chief engineer at Cheltenham, sends us an illustration, shown in Fig. 1, of the Manchester-street showrooms specially decorated for the celebrations. This showroom is in a building which has a reputation in the district for extreme ugliness. We believe it is locally known as "the prison." With its festoons of electric lamps it has, however, been transformed into something of a fairy palace, that is if the illustration is anything to go by. The scheme has been tastefully carried out having

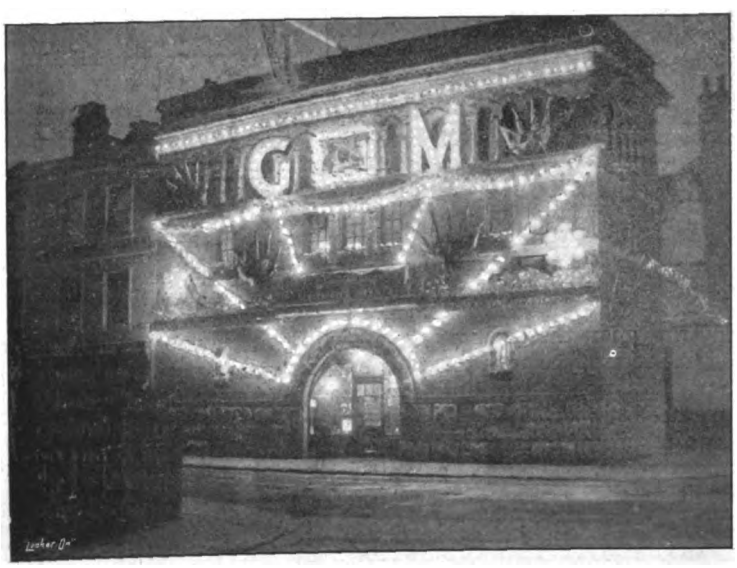

FIG. 1.—THE CHELTENHAM SHOWROOM.

regard to the configuration of the building itself, and we must compliment Mr. Bache and his assistants upon the result.

Mr. R. W. Phillips, the engineer of the Bedford Borough electricity works, has also been good enough to send us particulars of the illuminations carried out in his district. These seem to have been upon the most elaborate scale on the river. The Weir bridge was fitted up with a large illuminated sign "GEORGE, 1911, MARY," surmounted by a large crown.

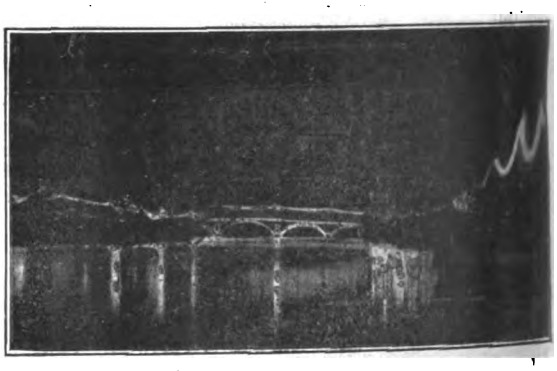

FIG. 2.—THE RIVER OUSE AT BEDFORD.

This could be seen from a good distance down the river. We illustrate in Fig. 2 the general effect on the river at night. Mr. Phillips informs us that the installation will remain up during the summer and be repeated on such gala nights as the Regatta on July 27. A special transformer is put up for the reduction of the supply pressure of 2,000 to 210 volts and 2½ c.p. lamps were used. The entire scheme of illumination on the river formed part of an elaborate river fête in which a procession of illuminated boats was a prominent feature. The illustration shows the passage of a number of these boats up and down the river. Practically every building on the banks seems to have been outlined with electric lamps, and we are afraid that our picture does but poor justice to the details of the lighting of these buildings. Appropriate colour effects were introduced into the scheme so that the public found nothing lacking in the way of variety. The townspeople appear to have entered enthusiastically into the scheme, and there can be no doubt that the electric service will reap great benefit from the display. It was particularly noticeable that throughout the illuminations gas cut a very sorry figure.

THE ELECTRICIAN COMMERCIAL AND INDUSTRIAL SUPPLEMENT.

C. & I. Supplement No. 93.] JULY 14, 1911. [Gratis to Subscribers.

THE FLICKERING OF GAS ILLUMINATIONS.

Now that the Coronation is over we have an opportunity of reviewing dispassionately the displays made by the three illuminants which figured most prominently in the celebrations—(1) electricity, (2) gas, (3) candles. As far as electricity is concerned, there can be no denying that the displays made in London and the provinces were upon a scale of magnitude and magnificence not previously attempted. As far as we can judge by the reports sent in to us there were practically no cases of fire due to electrical causes as the result of bad workmanship or the action of bad weather upon the illumination material. In fact, the electrical industry can pride itself upon having secured a huge success for electric lighting and also upon giving to the celebrations an after-dark display which would not have been possible with any other illuminant.

The advocates of gas must in great measure lay the blame upon the clerk of the weather for the sorry figure cut by their carefully-planned devices and schemes. In London the principal evenings of the celebrations were marked by windy and wet weather, and these two components of the elements were responsible for the painfully complete failure of the gas display. Where open piping with punched holes was used, either for outlining a building or for lettering or some heraldic device, the effect of the wind was to either blow out the whole of the jets or to cause various sections of these to light up at spasmodic intervals, the sections themselves being badly "out of phase." For instance, in Piccadilly "God Save our King and Queen" was a huge gas device surmounting one of the buildings overlooking the Green Park, and the combinations of letters which the wind permitted the gas to display were always amusing but never dignified. In the provinces much the same thing happened. In Brighton one of the large hotels attempted to display Britannia and the Lion and Unicorn in gas jets. A local correspondent informs us that Britannia has never cut such a sorry figure before, it being possible for her to show on occasions only one or two prongs of her trident. The lion and the unicorn remained practically invisible beasts except for a stray whisker,

a hoof or a horn, according as the caprice of the wind permitted. As far as we are able to gather the gas interests were able to create a record in the perfuming of the scenes of their would-be celebrations with the now well-known and easily recognisable odour. Where an attempt was made to protect the gas flame with small coloured globes the result was practically the same, the rain quickly filling up the globes and effectually dousing the gas jet. Surely our gas friends should see in these signs and portents "the writing on the wall." If the elements are arranged against them in this unfriendly way they should realise that the day of gas as an illuminant is gone. We are quite prepared to give them their legitimate position for heating and cooking, but so far as lighting is concerned we can only say "Let the public decide," and if this decision is influenced by the Coronation illuminations then the day will not be far distant when the users of gas as an illuminant will be legally proceeded against. As far as candles are concerned their chief merit lay in the fact that they came to the rescue of the gas people in the predicaments above referred to.

C.T.S. HOUSE WIRES.

We are all familiar with C.I.V., B.D.V., I.D.B., E.M.I., J.C.P. and other magic initials, which we have come to associate with either persons, deeds or things. The latest arrival is "C.T.S." which the St. Helens Cable & Rubber Co. would like every electrical contractor and station engineer to impress deeply upon his mind. The magic initials stand for Cab Tyre Sheathing, and they refer to a new class of insulation which is being put forward for the protection of exposed cable. The material was successfully experimented with for trailing cables for mines and dock cranes, and steps are now being taken to introduce this class of insulation for house wiring. The insulation is extremely flexible, and the branch wiring conductors recommended are a pair of 22/36 s insulated with pure and vulcanised rubber and enclosed in a cab tyre material tube $\frac{1}{16}$ in. thick at the thinnest places, and having an overall diameter of $\frac{5}{16}$ in. In appearance the flexible resembles compo gas piping, but it has a leaden colour. The makers claim that the material is both cable and conduit combined, that it can be run in any position, being simply cleated or stapled up, that it is quite flexible, that it cannot possibly be kinked even deliberately, that it is water and shock proof, that it occupies a minimum of space, and that it is impossible to injure it without cutting tools. If the sheathing is cut and the cord violently twisted and bent, the cut does not tend to spread. After a lighted match has been applied to the material it burns quietly, the flame travelling slowly along. The actual sheathing is not relied upon in any way as a conductor. It simply forms a flexible mechanical protection. In the use of the material for house wiring there is an enormous saving in the cost of labour. Under the score of durability, the makers have submitted the material to the action of ozone for long periods without any destructive effects. We understand that Messrs. Callenders and Messrs. Siemens Bros. & Co. are manufacturing this class of conductor under licence from the St. Helens Cable & Rubber Co.

BUSH ROLLER CHAINS.

We are now able to give illustrations of the new pattern of power chain which Messrs. Hans Renold are putting on the market and which we briefly described in a recent issue. Fig. 1 shows the spring clip joint which was introduced primarily for motor-cycle work, where the clearance between the bolt head and the nut was small. It comprises a side plate and two studs which are grooved round the ends where they project through the detachable sideplate. The plate is secured by a clip sprung into place in the stud grooves. Fig. 2 is a section through the bowl and brush and roller chain and is intended to compare these two types. The hatched portions in the sections illustrate the relative bearing surface of the two chains. In the bowl type of chain the plates were threaded on the rivets and spaced apart by bowls or rollers, the plates and rollers bearing directly on the rivets, there being only the

thickness of the two inner plates as a bearing surface. A chain of this type will lose its pitch very rapidly. In the bush pattern it will be seen that the improvement consists in placing the inner plates on the bushes in such a way that these turn on the rivets fixed to the outer plates. The full length of the bush is therefore used as a bearing surface and the life of the chain is increased by at least several 100 per cent. The wearing surfaces are also case-hardened in the bush roller, but this is not possible in the bowl pattern of chain.

THE PRICE OF METAL LAMPS.

We have asked repeatedly in our Queries column if there is to be a reduction in the price of metal lamps this season. So far the lamp makers have vouchsafed no reply. They evidently prefer to leave the matter in the hands of electrical contractors, judging by the adjoining photograph which has been sent to us by an enterprising contractor in Brighton. The sandwich men shown in the picture have been parading the late scene of the I.M.E.A. Convention with announcements to the effect that reliable metal lamps can be purchased 230 volts at 2s. 6d. and 115 volts at 2s. This is a reduction with a vengeance. It is a pity that the coup was not arranged to startle the engineers who visited Brighton for the convention proceedings, but perhaps the contractor was anxious that they should all reach their respective homes in safety. From enquiries which we have made we gather that the lamps in question are supplied by the Gabriel Lamp Co., who inform us that as a result of their improved methods of manufacture they can offer a lamp which will show them a reasonable margin of profit at the prices mentioned, and at the same time maintain the standard of efficiency and life which we have learned to expect from the more high-priced and better known lamps. We also gather that exhaustive tests of these lamps have been made by the Corporation Electricity Department which have been in every way satisfactory, and they have not hesitated to recommend them to their consumers. This certainly lets a little side-light into that part of Mr. Christie's Presidential Address to the I.M.E.A. with reference to selling powers, &c. So long as there are contractors prepared to assist the supply undertaking by popularising electricity and attacking the gas interests, they may expect, and no doubt will obtain, every consideration from the engineers, and Brighton is to be congratulated on having taken the initiative in this matter.

The fight with gas has been borne in mind in the lettering on the sandwich boards, the passer-by being admonished upon its use and warned not to poison himself by allowing it in the house as an illuminant. As far as we ourselves are concerned, we have no opinion to express. The engineers at the Convention were of opinion that the serious effect of the metal lamp upon the load factor of the station has now been counteracted by the ever-increasing power load. If this is the case then the more metal lamps which the station man is able to connect the better, particularly if the question of the cost of a new service does not enter into the question. In the early days of the metal lamp the cry was the more lamps per existing consumer the merrier. The problem for the station men, however, has been the small 5-light consumer who wants a service and who has been, and no doubt still is, a thorn in the side of the undertaking. Setting these things upon one side, however, and looking at the question purely from the point of view of supply and demand, the case for a reduction in the price of metal lamps can be made a strong one. The matter seems, however, to be left to the larger metal lamp manufacturers, and they will doubtless decide, probably at the time of the Olympia Exhibition, what policy they will adopt. In the meantime it will be interesting to follow the results of the price-cutting campaign at Brighton.

NEW CATALOGUE.

Light Accessories.—Section L of Messrs. D. H. Bonnella's catalogue has just been issued. This deals with light accessories. The apparatus described comprise switches, wall sockets and pushes for flush and surface work. A feature is made of flush switch fronts, both of the plain and ornamental type. These designs are worth the careful study of electrical contractors, particularly those who have the opportunity of doing work in good residential districts or country houses. They can be made to harmonise with surrounding decorations.

IFS AND QUERIES.

Will the new C.T.S. flexible be mistaken for the garden hose during the summer months?

If the Contractors and Supply Station men would only settle their differences and get to serious business.

Cannot the General Electric Co. arrange for each of the competitors in the London-Brighton walk (July 29) to carry an Osram lamp, the Osram Cup which is being presented by Mr. H. Hirst to go to the man arriving first with his lamp intact? (No swopping of lamps en route.)

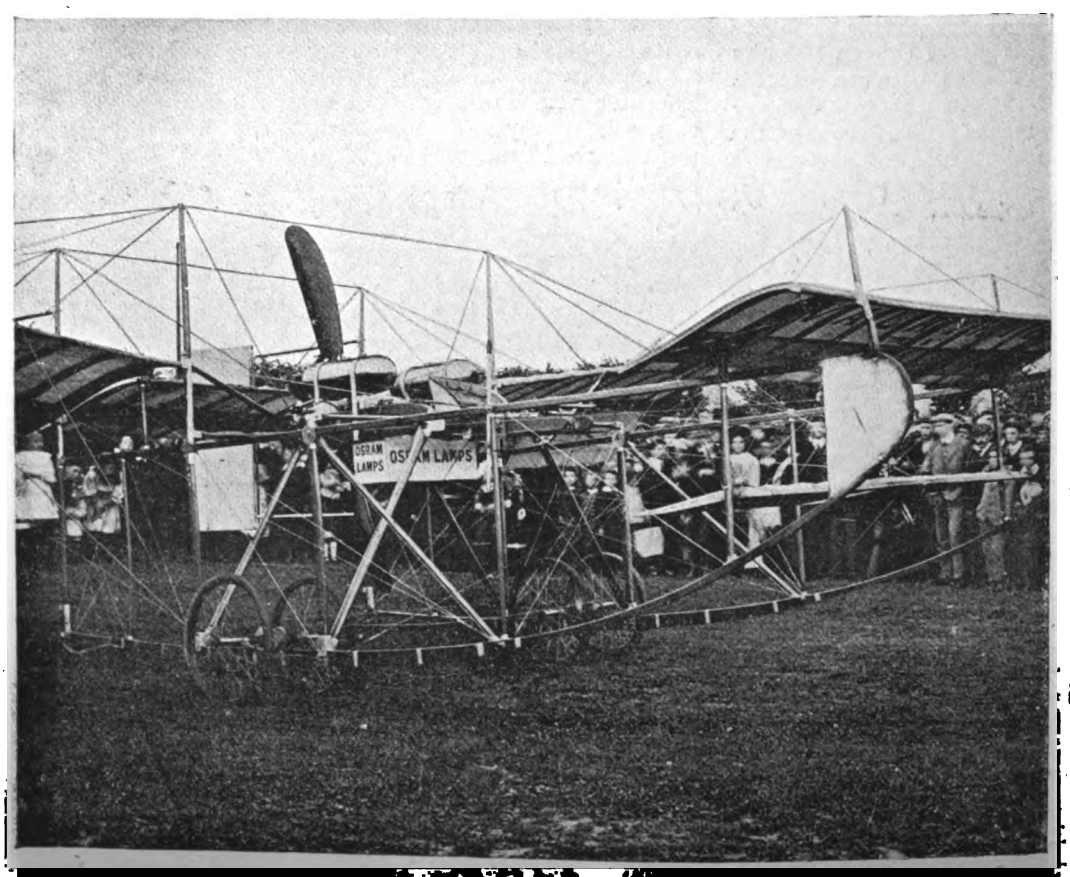
AERIAL DELIVERY OF OSRAMS.

For I dipt into the future
Far as human eye could see;
Saw the vision of the world
And all the wonder that should be.

Saw the heavens fill with commerce,
Argosies of magic sails,
Pilots of the purple twilight,
Dropping down with costly bales.

"*Alf.*'

And Tennyson was not far wrong, though he could not be expected to foretell that the first of the costly bales to be delivered by air would be a parcel of Osram lamps, although it is extraordinary that his prophecy should come strictly true both in this respect and in regard to the purple twilight. When Mr. Barber made his flight from Shoreham to Hove last week he landed just as the sun was setting. His box of Osram lamps may justly be here looked upon in the light of costly bales. The above remarks are supplementary to those which we made last week upon this epoch-making event, and we are now further able to illustrate the incident after the successful landing of the aeroplane. The illustration shows the box of Osram lamps securely tied under the aviator's seat and the dense crowd gathered around the machine. It is particularly gratifying to note that the machine is an all-British one, and, furthermore, that the lamps delivered were manufactured at Hammersmith.



THE "OSRAMPLANE" IMMEDIATELY AFTER LANDING AT HOVE WITH ITS LOAD OF OSRAM LAMPS.

ELECTRICAL IRONWORK.

The extent to which cast-iron is used by the average station engineer in connection with his service boxes and street lighting is shown in a marked degree by the new list which W. Lucy & Co. (Ltd.), Eagle Iron Works, Oxford, have just issued. This list is entitled "Electrical Ironwork," and contains a description of the principal products of the company. It is divided into sections which are devoted to street lighting, fuse boxes, joint and service boxes, disconnecting boxes, feeder pillars, time switches, speed and frequency indicators, and steel storage shelving. In the street lighting section will be found a number of interesting illustrations of lamps and lanterns suitable for side street lighting with metal lamps. The variety is so great that it is impossible to select any one type as being particularly distinctive. After all, the design of the street lamp-post should be made to harmonise with the architectural features of the district, and we think that engineers who make a selection on this basis will be able to choose something from Messrs. Lucy's new list to meet their requirements. In particular they will be interested in a high candle-power street lighting lantern which will accommodate four 100 c.p. or three 200 c.p. lamps. It is fitted with a shaped enamelled reflector which has been designed to give efficient light distribution. The lantern is also properly ventilated and ample vibration supports are provided for the lamp holders. Engineers will also be interested in an automatic controlling gear for street lighting which we illustrate in Fig. 1. This has been designed for attachment to the top of the ordinary side street standard. It comprises a compact and serviceable arrangement of a time switch and an ordinary switching fuse. These accessories are enclosed in an iron case which is fitted with a spring door and rendered water-tight by compressing a rubber casket between the lid and the box. Either damper fuses or Zed fuses can be used. The ordinary switches and fuses are intended for use in areas which are liable to dense fogs, and they enable the street lighting authority to turn on a number of lamps at irregular intervals which the time switch does not usually provide for. The hand operated tumbler switch is in parallel with the time switch.

In the service box section engineers will find a great variety of boxes for practically every type of cable now in use. The triple-concentric box is of particular interest. Arrangements are made in many of the boxes for taking out two services, the

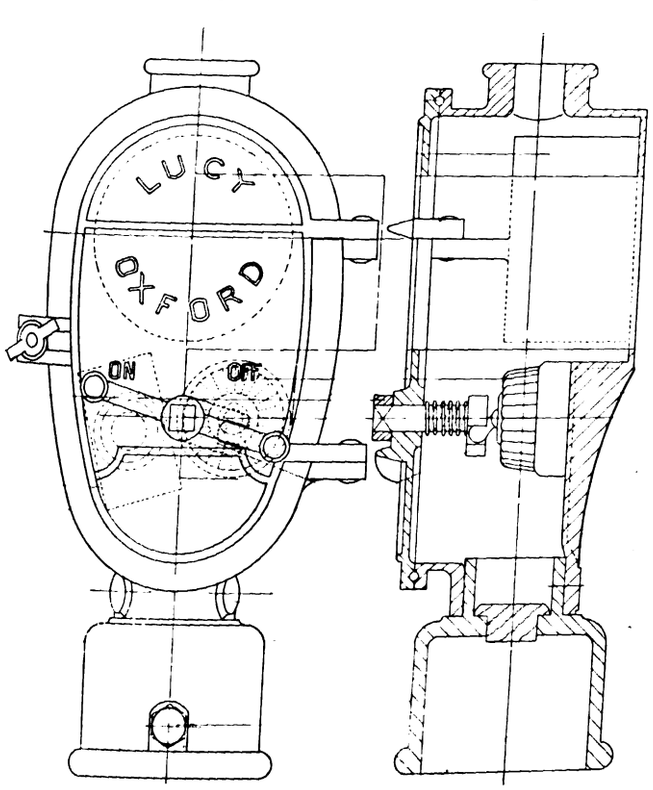
fittings for the second service being available when it is required to make an additional connection. A line of lead service boxes is also offered and practically any shape of this pattern of box can be supplied to order. The feeder pillar section should also be turned to with interest by supply station engineers. High-tension feeder pillars are dealt with as well as the more ordinary low-tension type. In the time switch section there is described the Arbiter type time switch, which comprises an oil switch with plug contacts and magnetic blow-out, the switch being operated by handwheel and clockwork mechanism. The switch can be turned on by the movement of the handwheel to the right and it is opened by giving a slight pull on the handwheel. When the clockwork is running over the restricted hour section the switch cannot be closed. The switch is made in two models, one for capacity of 50 amperes at 500 volts and the other for 25 amperes at the same pressure. The clock will go for 35 days in the large type and 16 days in the small one.



TIME AND AUXILIARY SWITCH FOR LAMP POST.

POLYPHASE INDUCTION MOTORS.

The vogue of the polyphase motor is constantly spreading and the utility of this useful power agent in industrial service has been considerably enhanced by the excellent work put into the machines by modern makers. The polyphase motor of to-day is essentially built for hard wear, and the makers as a rule spare no pains to design the machines upon rugged lines. Messrs. Siemens Bros. Dynamo Works have paid special attention to this class of machines and they offer them in sizes from the smallest to the largest and for any voltage or frequency. The usual scheme of classifying the motors into protected, ven-

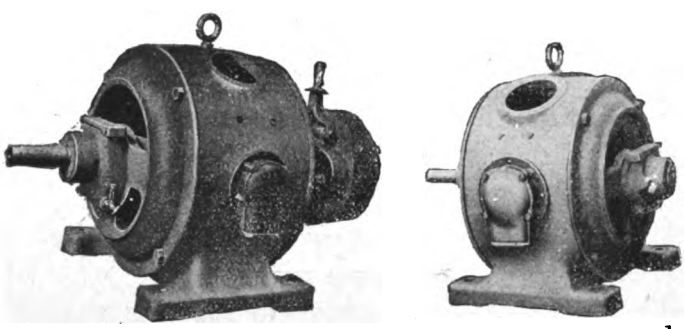
tilated and open types has been adopted, and the temperature limits specified by the Engineering Standards Committee are complied with in the design. A generous overload rating is



also allowed for, this varying from 25 to 100 per cent., according to the type of machine. The power factors for which the machines are listed are for rated full load or any of the frequencies specified. The current consumption of the machines is given by the formula

$$C = \frac{746 \times \text{B.H.P.}}{1{\cdot}732 \times \text{voltage} \times \text{power factor} \times \text{efficiency}}.$$

For two-phase motors the formula is

$$C = \frac{746 \times \text{B.H.P.}}{2 \times \text{voltage} \times \text{power factor} \times \text{efficiency}}.$$

We illustrate the squirrel-cage and slip-ring type motors here-with. Where machines have to run in damp places, such as breweries and mines, or in humid climates, the insulation is treated with damp-proof compound at a small extra charge. The machines can be supplied with overhung pulley or outdoor bearing as required.

THE WEEK'S TRADE LITERATURE.

HENLEY'S RUBBER CABLES.—A handsome price list has been prepared by W. T. Henley's Telegraph Works dealing with all classes of their rubber cables. Special attention is directed to a high-tension and extra high-tension cable section in which cables for from 2,000 to 11,000 volts are dealt with. Special sections are also devoted to aerial cables, flexible dynamo and motor connections, motor car flexibles, flexible trailing cables for portable machinery, especially in mines, ozone and fireproof cables, cables for chemical works, high temperatures and tropical climates. The makers also call attention to the new type of protection in the Home Office flexible section, this comprising a hard cord braiding, which is exceedingly durable covering, and obviates the necessity for metal armour, with its earthing complications. We may remind our readers that Henley's are backed by 58 years' experience in the manufacture of cables and that their clients have the advantage of such experience.

THE ELECTRICIAN COMMERCIAL AND INDUSTRIAL SUPPLEMENT.

C. & I. Supplement No. 94.] JULY 21, 1911. [Gratis to Subscribers.

C.T.S. HOUSE WIRES.

A CORRECTION.

The St. Helens Cable & Rubber Co. (Ltd.) have pointed out to us a serious mistake in the notice of their new cab-tyre sheathed cables and wires which appeared in our last issue. The C.T.S. covering was spoken of as an insulator, whereas it is intended to act as a protection for the insulated conductors. We also referred to the material as being shock-proof, whereas the makers claim that it decreases the risk from shock. The chief error to which we would direct attention is, however, the sentence in which we stated that the actual sheathing was not relied upon as a *conductor*. This is, of course, an obvious mistake for *insulator*, and we much regret that it should have crept into the notice. We feel sure that our readers will have detected the mistake, but we take the first opportunity we have had of correcting it.

NEW TRADE LITERATURE.

The Globe Standard Flame Arc.—Particulars are being sent out by the Globe Electric Co. of the Globe standard flame arc lamp for direct-current and alternating-current circuits. The details of this lamp have been published in our columns on a previous occasion. We would recommend interested contractors and engineers to apply for pamphlet S. 50 which will give them these details and prices.

New "Onewatts."—A 300 c.p. "onewatt" lamp in spherical bulb is now on the market, and Siemens Bros. Dynamo Works have ready a list which gives particulars and prices. This new pattern of lamp is 12 in. long and 8 in. diameter and is supplied only with "Goliath" Edison Screw Cap. Particulars are also given of holders for these lamps. The lamp filaments are drawn tungsten and are supported on tantalum hooks.

Spookie Shades.—The popularity of "spooks" and spookie shades is being well maintained (or at any rate the latter are deservedly popular) and Simplex Conduits Ltd. are issuing a new list concerning them. The styles include patterns which are now household words, particularly the "old Nuremberg" lanterns, and a new series of spookie screens for candle and bracket lamps is offered. These must be seen to be appreciated.

Loom Motors.—A line of small polyphase motors for the direct driving of looms is being put on the market by the Union Electric Co. These motors are high-efficiency machines and should make headway in textile districts.

MACHINE TOOL MAKERS' ASSOCIATION.

Particulars have reached us of a new Machine Tool and Engineering Association which has just been formed, more or less as the outcome of a meeting of machine tool makers at Olympia, 1910. The association has been registered as a limited company, and its object is to exercise some control over the organisation and frequency of exhibitions. It is felt that the latter are being overdone, and already it has been decided to hold one exhibition in 1912 instead of two, one in that year and another in 1913. The offices of the new association are at 104, High Holborn, London, W.C., and the secretary is Mr. H. G. Williams, who is backed by a strong committee composed of the principal tool makers.

WATERTIGHT WALL PLUGS.

The Home Office Regulations have had a considerable influence upon manufacturers in the production of satisfactory wall plugs and sockets for use in damp situations. Messrs. A. Reyrolle & Co. send us particulars of a new pattern of wall plug and socket which complies with the Home Office Regulations, and it is stated by the makers to be suitable for all

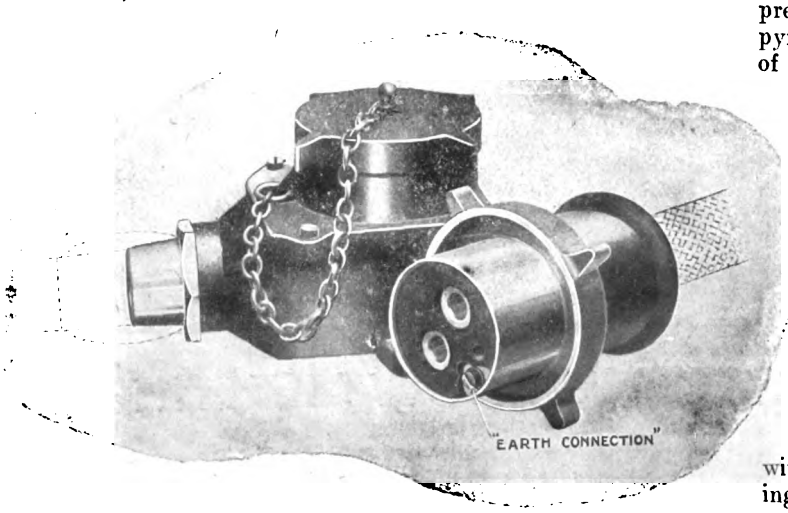

FIG. 1.—50 AMP. REYROLLE WALL PLUG.

damp positions. Fig. 1 illustrates a pattern suitable for a 50-ampere circuit, and it will be noticed that the design is on substantial lines, and the makers guarantee the plug to be strong and serviceable in use. It is recommended for cranes and heavy portable tools on dock sides, shipyards, engineering works, &c. It will be seen that an extra pin is provided for the earth connection, and this makes contact before the current carrying pins, and also breaks contact after them. The contact

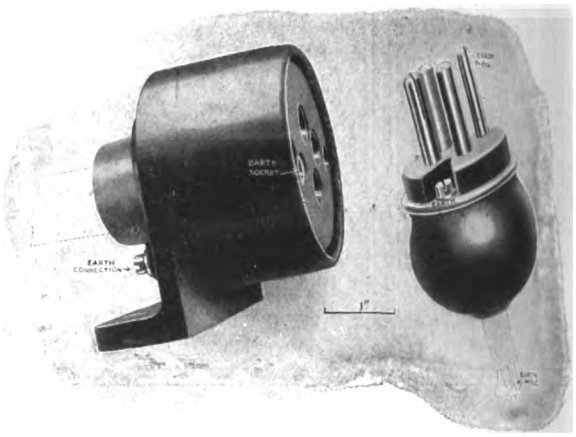

FIG. 2.—DUST PROOF WALL PLUG.

surfaces are of ample proportions. Fig. 2 illustrates a 10/20-ampere dustproof type which will be found useful in dry situations.

THE RUBBER EXHIBITION.

Three years have elapsed since an exhibition devoted exclusively to rubber growing and rubber products was held in London. The exhibition was held this year at the Agricultural Hall, and was even more interesting and representative than its predecessor. The electrical engineer is specially interested in rubber production, and although he relies to a considerable extent upon substitutes for the insulation of cables and other pieces of electrical apparatus, at the same time he must still depend to an enormous extent on this natural product. We gather from the prospectus of the exhibition that the Governments of rubber producing countries have accorded their support to the exhibition, and have spent considerable sums in order that the cultivation and preparation of the rubber product as carried out in their particular districts may be accurately presented to the public. The exhibits of Brazil and British Malaya, of Ceylon and India and the Dutch Colonies were of particular interest. As we remarked in a previous issue the Brazilian Government exhibited an immense pyramid of rubber comprising 500 56-lb. balls, the total value of this being estimated at £8,400. According to a report made up to June 30, 1911, 21,680 tons of Brazilian rubber have been delivered into Manaos, this including the deliveries from Peru, Bolivia and Venezuela. It is stated that upwards of 50 millions are invested at the present time in the rubber industry in the Malay Peninsula, and that there are 400,000 acres of Para rubber under cultivation. Last year the export of rubber from this district was 6,500 tons, and in the first four months of this year was nearly 3,000 tons. Southern India, British Guiana, British East Africa, the Gold Coast and Queensland, also the British West Indies, contributed special exhibits. Germany and her colonies were also represented, the rubber industry dating back to the year 1829. Not only was the rubber product dealt with in the exhibits, but there was a fine display of rubber working machinery. In this section British engineering firms were

shown to the best possible advantage. They appear to have achieved immense success in the development of this class of plant, and their exhibit was a predominating feature of the engineering section. Germany and France also made exhibits.

Our readers who are interested in this question from a financial point of view could not do better than turn to "The Times Finance, Commerce and Shipping Supplement" of the 7th inst. This deals with the subject in an exhaustive manner, and at the same time interspersses among the financial items a number of interesting articles dealing with the uses and importance of rubber.

AUTOMATIC FRICTION CLUTCHES.

We referred last week to the publication by Messrs. Thomas Broadbent & Sons, Huddersfield, of a new pamphlet on their automatic centrifugal friction clutches. We are now able to give some additional particulars of this interesting device. Fig. 1 is a section through this clutch and shows the spring controlled shoes for regulating the speeds at which the driving commences. It will be seen from this that the clutch comprises a central boss keyed to the motor shaft and carrying friction shoes or slippers in suitable slides. Under the action of centrifugal force these shoes move outwards as the speed of the motor increases, and they gradually engage with the internal rim of the clutch pulley, by which the power is transmitted to whatever machinery is being driven. The acceleration of the outer portion of the clutch is quite gradual and when driving at full speed there is no slip. The clutch can, however, be designed to slip under overload, and in this capacity checks undue strain upon the motor and shafting. The clutch acts as a flexible coupling, in that it prevents shocks or load variations from being transmitted to the motor. The renewable portions of the clutch are comparatively inexpensive and can

be replaced in a few moments. They have a long life under the most severe working conditions. The form of clutch illustrated in Fig. 1, in which springs are used, is made so that the engagement of the motor with the outer portion of the clutch takes place only at a certain predetermined speed. This form

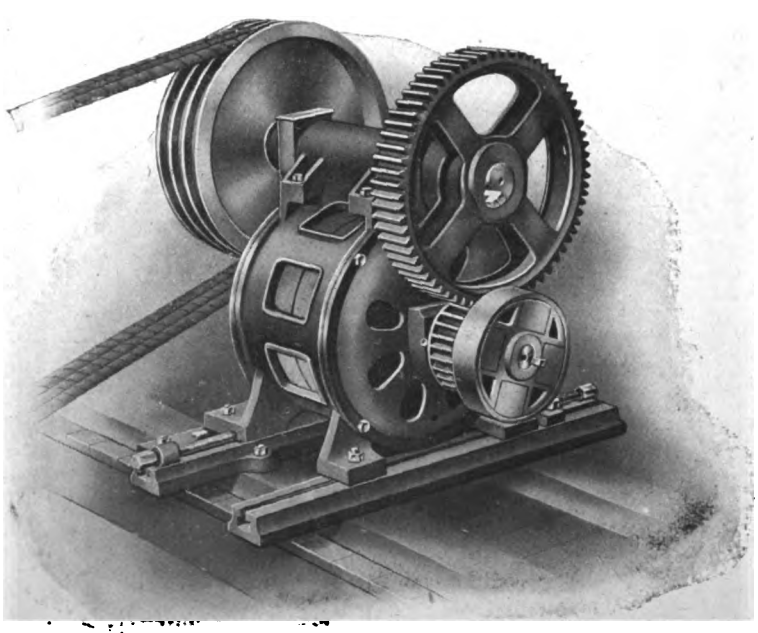

FIG. 3.—25 H.P. BACK-GEARED MOTOR DRIVING THROUGH FRICTION CLUTCH.

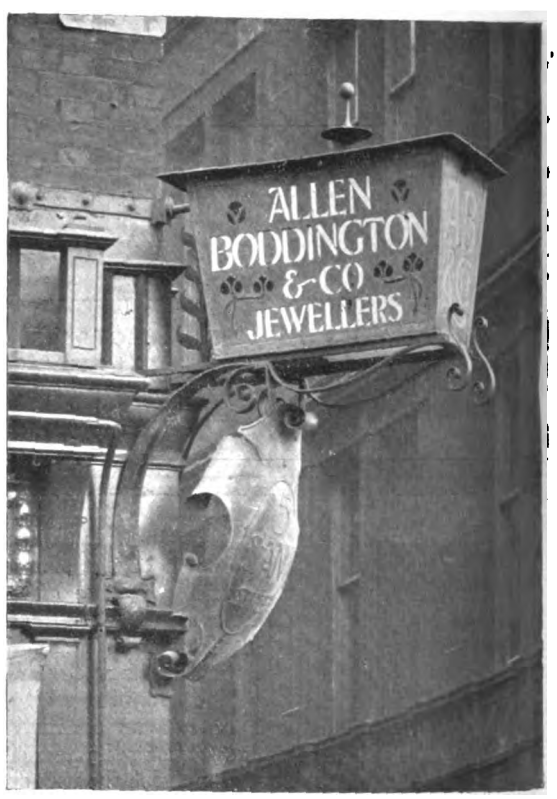
is recommended for one-phase motors. Fig. 2 illustrates a pair of 50 H.P. squirrel-cage induction motors arranged to drive line shafting by ropes. Fig. 3 is an illustration of a 25 H.P. squirrel-cage motor back-geared to a rope pulley for driving shafting. A star delta starting switch is employed and the clutch is designed to slip at about 75 per cent. overload. We understand that Messrs. Broadbent have fitted a number of clutches to capstans, and that they make a practice of supplying them with their alternating-current hydro-extractor motors. The clutches are made in sizes from ½ to 1,500 H.P., and Messrs. Broadbent will be glad to furnish additional data to interested inquirers.

SIMPLEX WINDOW SIGNS.

The production of the artistic and at the same time useful advertising sign for tradesmen has engaged the attention of electrical manufacturers for some time past. Messrs. Simplex Conduits have recently evolved a pattern of sign which should find considerable favour among shopkeepers. It can be supplied in the hanging or bracket forms and may be either of the



SIMPLEX ARTISTIC BRACKET SIGN.

open or closed-back type. The illuminating units may also be fitted with holophane reflectors if required. The lettering of the sign is in artistic open-work of the metal face and is backed by opal glass behind which is the lamp itself. This glass serves as a reflector to light up the goods in the shop window. A new list (S.1) has just been published by the company and in this are reproduced many artistic designs of shop signs. We are sure that this will attract the attention of all up-to-date tradesmen, or of that class of shopkeeper who is engaged in the modernising of his establishment. The present-day trading concern must be fitted up to attract the public eye and the main streets of our great cities testify to the care and thought which are expended on the design of shop windows, facias and fronts. In schemes of this character the Simplex sign should find a prominent place.

A NEW OIL ENGINE.

The interest taken in the Papers on the internal combustion engine read at the I.M.E.A. will be sustained by the introduction of new patterns of oil engines at this time. We mentioned the 2-cycle Willans-Diesel engine, and are now able to give particulars of a 2-cycle semi-Diesel engine which Petters Limited have put on the market. This differs from the ordinary Diesel in that the high compressions which are utilised in that engine are not made use of in this particular engine, the compression only reaching a maximum of 160 lbs. pressure. Advantage is, however, taken of this particularly high pressure in combination with a self-heating and vaporising device to simplify the explosion of the mixture, and at the same time to make it possible to employ crude oil or petroleum residue. The engine is of the high-speed type and may be direct-coupled to a dynamo. The smallest engine at present made is 10 H.P., and the largest shown in a recent list is 50 H.P. Before starting the engine the vaporiser is heated by a small lamp, and after the engine has been running a few minutes this is extinguished. As we have already said the engine is of the 2-cycle pattern, and at the end of the firing stroke when the exhaust ports are opened the burned gases are expelled through the ports by the inrush of air which is compressed in the crank chamber. This satisfactorily clears out the compression space. At the end of the compression stroke the fuel oil is pumped into the vaporiser under pressure and being mixed with the compressed air satisfactory combustion is obtained, and the makers claim that there is no deposit or residue after the explosion. The oil consumption is stated to be ½ pint per brake-horse-power per hour. Taking the price of crude petroleum at 50s. per ton, although it may be obtained cheaper at seaports, the cost of running for fuel alone would be in the neighbourhood of ⅛d. per brake-horse-power hour.

An inertia pattern governor is fitted which operates on the fuel pump, and the makers claim that the engine runs sufficiently smoothly to be direct coupled to dynamos for electric lighting. Water-cooling is arranged for, and a rotary pump driven from the crank shaft circulates the water through the cylinder jacket. The main bearings are ring oiled, and the piston and cylinder, also the big end of the connecting rod, are supplied with forced lubrication from a positive feed pump. Provision is made for self-starting the engine from a compressed air "bottle," which is kept charged up to a certain pressure, shown on a gauge, by a portion of the air which is compressed in the cylinder itself. When the desired pressure is reached in the bottle it can be cut off from the cylinder by the closing of a small valve.

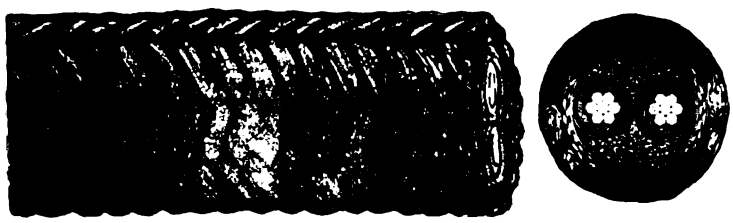
CORD BRAIDED FLEXIBLES.

The use of portable electrical apparatus, particularly in mines and industrial establishments, has extended so rapidly that the cable makers have had some difficulty in keeping pace with suitable "flexibles" for the supply of energy to the apparatus. W. T. Henley's Telegraph Works have followed closely developments in this direction and have produced a class of cord-braided flexibles which they have found to answer admirably for hard industrial service. By dispensing with the metallic covering to the flexible the need for elaborate earthing fittings is obviated. Where the regulations stipulate that the case or carcase of the apparatus shall be earthed, then an earthing wire can be carried through the flexible. This particularly



ELEVATION AND SECTION OF CORD BRAIDED FLEXIBLE.

applies to hand lamps where the metal guard and fitting must be earthed. The standard specification for vulcanised flexible is as follows:—"Conductors composed of h.c. plain copper wires 0·006 in. diameter, lapped with cotton insulated with two layers of V.I.R. and vulcanised together. Earthing conductor composed of h.c. plain copper wires 0·006 in. diameter braided with cotton and compounded. Three cores (two insulated and one earthing core) laid up circular with jute wormings strongly braided and served overall with preservative compound. Insulation resistance 300 megohms per mile after a minute's electrification." These flexibles are offered in sizes from 22/38's to 114/38's. Electric power engineers and contractors should apply to Henleys for samples.

OSRAMS AT A CREMATION.

We are now so accustomed to the Osram lamp as a part of our vital essence that we may express no surprise to find it being used to illuminate a funeral ceremony. We do not yet conduct illuminated funerals in these civilised climes, but the fashion set at the cremation of King Chulalonkorn may perhaps be followed in this country at no distant date. We are informed by the General Electric Co. that the funeral rites for the late King were conducted in the light of Osram Lamps, and that upwards of 100,000 c.p. of illumination was displayed. The Eastern agents of the G.E.C. state that the Siamese papers referred to the brightness of the scene as indescribable. This we can readily understand if so large an amount of light was available. The illustration below will give some idea of the imposing nature of the ceremony, but of course it can only do

100,000 C.P. OF OSRAMS AT A KING'S FUNERAL.

scant justice to the actual brilliance of the scene. The Osram lamp appears to be maintaining its reputation for records in the novelty of its uses.

Howden & Co., one 1,000 kw. turbo-alternator; Randfontein Mines, one 265 and one 40 B.H.P. alternating-current motors; La Plata Trams, ten 200 tramway controller equipments.

ALUMINIUM FOR TRACTION SERVICE.

The importance of aluminium as a conductor for more specific purposes than transmission line work is being emphasised more and more every day. The British Aluminium Co. are constantly issuing literature pointing out the merits of aluminium for 'bus bars and special conductors in power houses, such as feeder and battery connections. They have recently sent us a reprint of an interesting paper by M. Mariage, of the General Omnibus Co. of Paris, in which data is given of the use of aluminium coils in place of copper coils in traction motors. The weight varies from 50 to 55 per cent. of copper. In the cost of manufacture there is also a considerable saving, it being shown that a copper coil weighing 68·2 lb. costs 89s. 2d. and an aluminium coil weighing 33 lb., 33s. 4d. In the renewal of the coil there was a saving in favour of aluminium of 15s. There does not appear to be any difficulty in the application of aluminium to this class of service, and doubtless an extension in this interesting direction may be looked for in the near future. The pamphlet in question is interesting to tramway engineers, and those who have not secured a copy should take an early opportunity of doing so.

SUN FANS.

The continuance of the tropical weather has brought the fan-makers out into the open. They have been chary of really coming out from their shells during previous years, because a cold snap has driven them in directly they have poked their heads out only a little way. The Sun Electrical Co., however, makes a full display with a wide range of fans extending from the smallest lamp-holder pattern to large ventilating types. The usual desk and bracket fans are listed, and there is practically no departure from previous types. Of some interest is that known as the revolving or oscillating fan, which is made for alternating-current circuits only. This has three distinct features. It is arranged so that it will oscillate within any given arc of the circle, the sweep of the fan being adjustable by reversing stops. By the removal of these stops the fan will completely revolve, presumably without tying the supply flexible into knots, and it can also be made to give a current of air in one given direction by placing the deflecting vane in a dead central position. This is a type of fan for which there should be a good demand. It is finished in black enamel with gold lines, with polished brass blades and guard and three-speed regulator. The company also list an oscillating fan base upon which an ordinary fan can be placed, and can thus be converted into an oscillating type. Among the novelties in the list we notice a reading lamp and a fan combined. In this case the motor is contained in the base of the lamp, and an extension shaft is carried vertically through the stem to the fan blades which are fixed outside the reflecting shade at the top. The fan consequently revolves in a horizontal plane and the air is deflected at any desired angle, distributing the cooling breezes without draught. Another novelty is a combined table fan and fruit dish. The fruit dish is a cut-glass bowl and is placed immediately above the fan blades on suitable supports. This can be supplied for alternating-current and direct-current circuits, either 100-110 or 200-230 volts. A copy of this fan list may be obtained from the Sun Company on application.

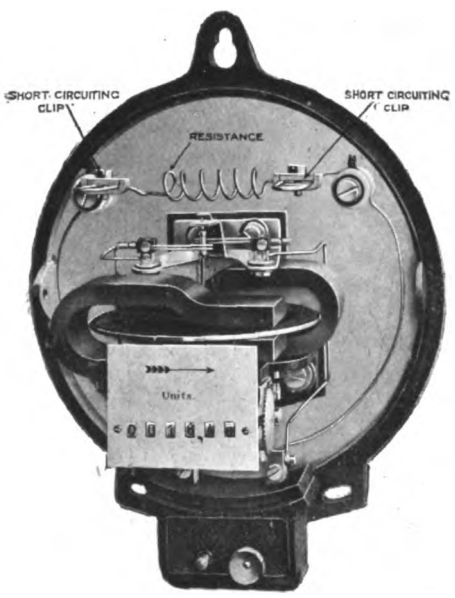
"FORTITER" METERS.

So high a reputation for excellence of workmanship has been achieved by the makers of the "Excello" arc lamp that they have turned their attention to the production of a direct-current ampere-hour meter. This is being put on the market by the Union Electric Co., who have given it the trade name of the "Fortiter" meter. The above illustrations show the chief features of the meter, these being the extreme lightness of the moving element (40 grammes is its weight), the absence of a locking device for transport purposes and the provision of a renewable hardened steel pivot at the lower or footstep bearing end of the spindle. The brake disc is of aluminium with turned up edge and the commutator is of silver, in accordance with standard practice, to ensure good contact. The footstep bearing is jewelled with a selected sapphire which is mounted in an oil-retaining brass cell arranged to slide into the bearing collar. The cell is supported by a retaining spring which can be swung round to allow the cell to be withdrawn, without altering the adjustment of the meter.

The brushes employed are of phosphor bronze faced at the free ends with gold wire, which is of course non-oxidising. With the silver commutator already referred to almost perfect contact between the fixed and moving connections is obtained. Light brush pressure only is needed, consequently the friction load on the meter is small. An integrating registering mechanism is fitted and this is operated from the armature shaft by worm and spur gearing. It is stated that the power required to move all the figure drums at once is only 1 per cent. of the load; this load is, however, seldom imposed.



"Fortiter" Meter with Case Removed.

Terminal Block of "Fortiter" Meter.

Back View of Dial Mechanism.

The permanent magnets which are essential to a meter of this type are of large sectional area, and are made of thoroughly "aged" steel. The armature will, it is stated, start at 1 per cent. of full load, and the watt loss is small, the series resistance having a drop of 1 to 1·2 volts at full load. The meter is designed for closest accuracy at about one-tenth of full load. The meter insulation is mica and the terminals are carried in a fire-proof insulating block. A sheet metal dust-tight case encloses the meter and terminals.

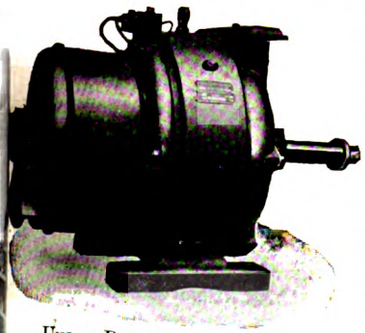
THE ELECTRICIAN COMMERCIAL AND INDUSTRIAL SUPPLEMENT.

C. & I. Supplement No. 95.] JULY 28, 1911. [Gratis to Subscribers.

CRANE MOTORS.

The Union Electric Co. is offering an entirely new line of motors specially rated for crane service. The motors are made for direct-current and alternating-current circuits, and are rated on the one-hour, half-hour and intermittent basis. Direct-current motors are either shunt or series wound. The former are recommended for single-motor cranes and passenger and goods lifts. The latter are used for traversing and swinging cranes, or traversing and rotating conveyors. For special service, compound wound motors with suitable controllers are recommended. The motors are constructed for the purpose of overcoming static friction. The momentary starting torque is equal to three times the normal running torque. Standard motors are made for 110, 220, 440 and 500 volts. The motors can be supplied in the open, enclosed ventilated, and totally enclosed types.



UNION D.C. CRANE MOTOR.

In the alternating-current machines the one-hour rating has been adopted. The momentary starting torque is equal to 2½ times the running torque, and under these conditions the current at starting is from 3 to 3½ times that taken at full load. For intermittent service these motors are supplied with wound rotors and slip rings. Standard machines are made for 50-cycle circuits, and the maximum voltage is 500. We illustrate herewith one of the direct-current motors, and a similar machine attached to a lift gear.

LARGE AND SMALL CAPACITY TIME SWITCHES.

The station engineer has already proved the utility of the time-switch for street lighting, and he has succeeded in applying it to trade consumers, particularly shopkeepers who employ this class of device for switching out lights which have been burning after business hours. The idea of utilising a switch of this class for the control of motor circuits during restricted hours has often occurred to English engineers, but we are not sure that any attempt has been made to put it into practice. On the Continent and in America there is a certain class of power consumer who keeps clear of the mains during peak load times. Whether he does this by time-switch or by

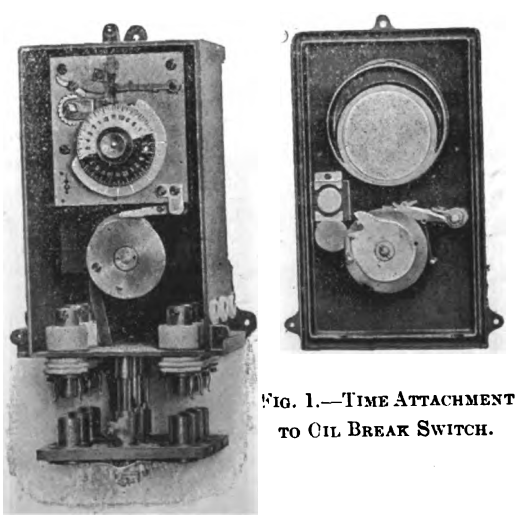

FIG. 1.—TIME ATTACHMENT TO OIL BREAK SWITCH.

arrangement we are not sure, but in any event there is probably a meter which changes over the rate of reading during restricted hours so that units consumed at that particular time are charged up at abnormal rates. We have received particulars of a pattern of high duty time-switch which is recommended for the control of motor and large capacity circuits somewhat upon these lines. Fig. 1 illustrates a switch of this class with the actual circuit-breaking device in an oil bath, the entire apparatus being enclosed in a cast-iron case. The switch proper is fitted with an accessory clock which will run for 35 days, this clock operating a dial which makes one revolution every 24 hours. Attached to this dial are curved discs which can be adjusted to lock the switch at predetermined times. A roller lever attachment rests on the periphery of the dial, and as

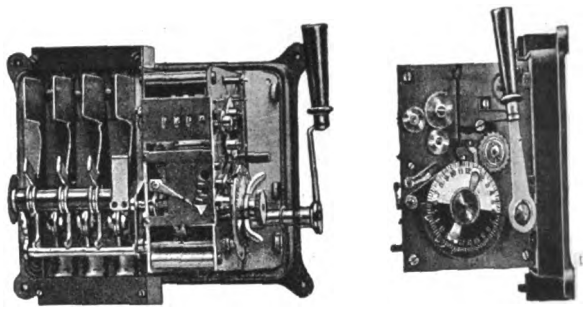

FIG. 2.—AIR BREAK PATTERN SWITCH WITH TIME ATTACHMENT.

long as this is maintained the switch can be opened or closed. When the limit period is reached the curved disc moves underneath the roller and raises it so that the switch itself is opened automatically and cannot be again closed. A large hand-wheel, which is not shown in the illustration, is used for the hand opening and closing of the switch. A counting mechanism can be fitted by which the number of hours during which the switch is closed can be registered. Similarly it is possible to fit an alarm bell which will ring some moments before the switch is timed to open automatically. A switch of the class illustrated is designed for a maximum capacity of 250 amperes. For a smaller pattern of motor an apparatus similar to that

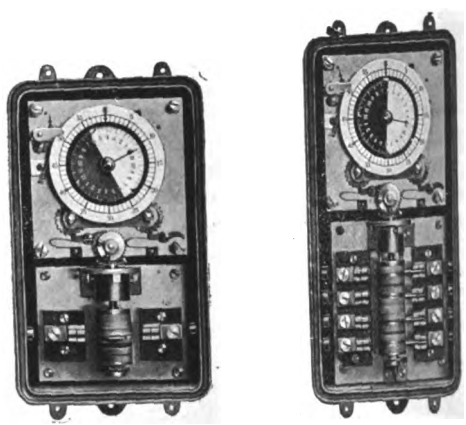

FIG. 3.—DRUM TYPE SWITCH WITH TIME ATTACHMENT.

shown in Fig. 2 is employed, the operation in this case being upon much the same lines, although the device is naturally smaller. In this instance the clock is arranged with the run of 16 days, and the consumer can wind up the clock himself, there being a device fitted by which warning is given to the running down of the clock. Should the clock be allowed to run right down the switch is automatically opened and cannot be closed again until the supply authorities are called in. Fig. 3 shows a smaller pattern of time switch which is recom-

mended for the control of street lights or all-night circuits in asylums, warehouses, jewellers shops, &c. This is designed for the maximum current of 30 amperes, and the clock is arranged for 14 to 16 days. There are adjustment pieces whereby the exact time of opening the switch can be predetermined. It is also possible to use switches of this class for change over from one set of circuits such as arc lamps to another, say incandescent lamps, and finally to extinguish the latter. These switches are being manufactured by Messrs. Novitas, Ltd., Zurich.

UNION LOOM MOTORS.

Developments in the textile industry are gradually bringing the small owner a firmer belief in the efficiency and reliability in the individual motor drive for looms and certain other special textile machinery. At one time the controversy raged around the great question of the collective efficiency of a large number of small motors as compared with the general efficiency of the scheme of modern rope drive. Slowly but surely the small motor has been gaining ground. In America, on the Continent, in India and in Japan electrical men have been installing small alternating-current motors for the individual driving of textile machinery. This experience has been brought to the notice of the Lancashire and Yorkshire Mill engineers and we understand that a combined movement is on foot for the more general introduction of motors of this class. In view of this fact interest attaches to a new list which the Union Electric Company are putting forward in which they describe their pattern "T" three-phase loom motors having an output of $\frac{1}{3}$ to $1\frac{1}{2}$ B.H.P. The pamphlet particularises upon the advantages to be gained by individual drive, and it then proceeds to refer in detail to the Union loom motor. Efficiency curves are published which go to show that as high as 87·7 efficiency can be obtained through a special motor of this class as compared with 76 per cent. with a motor which has not been specially designed. A number of interesting figures are given. A $\frac{3}{4}$ H.P. motor is assumed to be running 10 hours per day. If energy is supplied at 2d. a unit the cost for 300 days for a 76 per cent. efficiency motor will be £15, 9s.; with a Union 87·7 per cent. motor this cost will be reduced to £13. 9s., or a saving of £2 for every motor installed.

The loom motor can be arranged to drive by (1) direct spur gear; (2) friction coupling; (3) worm gear; (4) chain gearing; and (5) belt driving. Of these means the belt is the most popu-

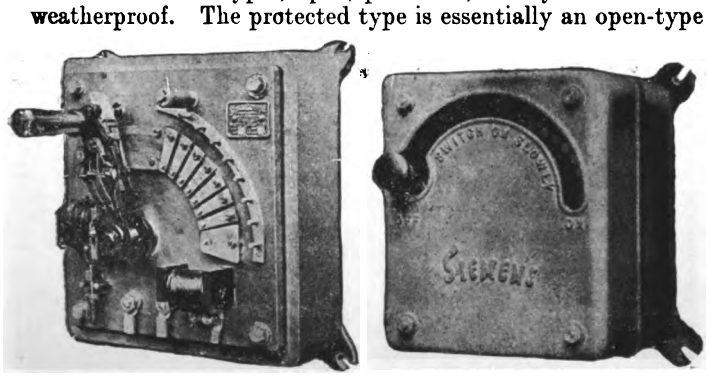
lar. The general construction of the Union motor follows the lines usually adopted with squirrel-cage alternating-current machines. The motors are standardised for 50 periods and run at a uniform speed of 1,000 revs. per min. Standard voltages are 110, 220, and the machines can be supplied with cradle suspension, and automatic spring controlled belt tightener. We illustrate a weaving shed in which a number of these motors have been installed for the individual drive of looms.

CONTINUOUS-CURRENT MOTOR STARTERS.

The continuous-current motor starters illustrated herewith are made in four types, open, protected, totally-enclosed and weatherproof. The protected type is essentially an open-type



C.C. Motor Starters.

starter with an iron cover having a slot through which the handle of the starting lever projects. The totally-enclosed type has a cast-iron cover provided with a glass window for inspection of the contacts, and handle outside the cover. The weatherproof type has a cast-iron cover with rubber packing and is provided with glands for cables.

All sizes have copper contacts easily renewable from the front, except in the case of the smallest sizes, where button contacts are used. Renewable rectangular contacts can be fitted at a slight charge. On all sizes, except the smallest, the overload release is designed to prevent further motion of the switch arm if the release operates during starting; this prevents the motor from being started up against an excessive overload.

The overload release can be set to act at various overloads. A hand trip is provided in all sizes except the smallest. All sizes from 6 B.H.P. can be fitted with a patent step-by-step slow motion gear. This ensures the motor being switched on slowly, so that the current at starting is kept within safe limits and the risk of overload on the motor during starting is reduced. The movement of the switch arm can only take place step-by-step, thus preventing sparking at the contacts and prolonging their life. Starters for outputs of 60 to 100 H.P. are fitted with carbon rollers, which protect the contacts against sparking.

The resistances are designed for starting a motor on full load once every 30 minutes, with a time of starting not less than 15 seconds for motors up to 25 B.H.P. and not less than 30 seconds for motors above 25 B.H.P. and up to 50 B.H.P. From 50 B.H.P. the starting time should be not less than about 45 seconds and for motors between 100 and 200 B.H.P. it should not be less than one minute. Full details can be obtained from Siemens Bros. Dynamo Works.

THE BOSTON ELECTRIC SHOW.

In our issue of June 16th we gave some particulars of the important electric exposition known as the "1912 Boston Electric Show" which is to be held during the fall of next year. We commented upon the various sections of the building in which the exhibition is to be held and referred to the boiler and dynamo room. We have since received a communication from the show authorities in which they say that this will shortly be shown as a motor generator room. The Edison service, as is practically common throughout the city of Boston, will be taken into the building, and it is stated that the electricity supply will only be available from this service. We also remarked upon the policy of the exhibition authorities in supplying carbon lamps free and making a charge for Mazda lamps. We looked upon this plan as placing an embargo on the metal lamp, but the exhibition authorities do not agree with us on this point. They write to say that the Boston Edison Company "were the first in the United States to forcibly and effectively permit the use of tungsten or Mazda lamps on lamps. We had 10,000 25-watt tungsten or Mazda lamps on our system when the largest number put out by any other company was less than 200. We have steadily sold Mazda lamps at the lowest prices and have been the first on every occasion to establish the new low level." The officials of the company have extended a hearty invitation to us to visit the exhibition and they also look for a good response from British manufacturing firms in the matter of actual exhibits. We hope that some of the originators of the exhibition will take an opportunity to visit Olympia, because we believe they will gain a considerable amount of useful information from a tour of the show.

A NOVEL CATALOGUE FILE.

Manufacturers are now accustomed to send out catalogue sections which deal with specific branches of their business. We receive these from time to time and they are usually

accompanied by some form of filing device which is arranged to take a full series of lists, perhaps a dozen or more in number. These filing arrangements vary in form and utility, but as a rule err on the side of undue complication. A simple form of file has just been sent to us which seems to solve the knotty problem completely. It is a box with flap lid and fall down right-hand side. The hinge for the lid is placed about an inch from the extreme left-hand edge of the box, and this portion forms a recess into which the small sectioned lists are dropped. There is no holing or clasping or any mechanism to operate. The flap lid is closed up by a spring button and the contents of the box are practically dust-tight. A list can be removed or replaced in a second. This neat device hails from Messrs. James Keith, Blackman & Co., 27, Farringdon-avenue, London, E.C., and enclosed in it are lists on the Keith fan, mechanical draught, belt-driven volume fans, electric volume fans, forges and forge blowing, high-pressure air blowers, the open Keith fan, electric table fans, all of which will be of interest to electrical engineers and contractors. Copies will be forwarded on request.

THE WEEK'S TRADE LITERATURE.

Dry Battery Ignition.—The merits of the dry cell for motor-cycle service are emphasized by a leaflet just published by Messrs. Siemens Bros. & Co., which gives particulars of a number of trials of motor cycles in which the Siemens-Obach dry battery was used. One of these runs may be cited—that from London to Exeter and back—a distance of 322 miles. One of the competitors who gained a gold medal used one of these dry cells measuring 4 by 4½ by 6½ in. He negotiated all the hills without failure or misfires, and no reserve battery was carried. The same battery was used for some months after this trial in a petrol consumption trial of the North-West London Motor Cycling Club, and it carried the winning competitor through successfully. The record of another battery measuring 4½ by 2-$\frac{9}{16}$ by 6½ in. is 764 miles of competition journeys, and we understand that this cell is still far from exhausted.

Governors and Governor Gear.—A pamphlet has been issued by Messrs. Wilson Hartnell & Co., Volt Works, Leeds, in which the Hartnell automatic expansion governor regulator is fully described. We understand that these engine accessories will be on view at the Olympia Exhibition Stand No. 255.

Motor Starters.—Messrs. A. Reyrolle & Co. have ready a pamphlet (No. 19) in which their lever type motor starters are priced and described. A feature of the starter is a patent resistance in which there are no wires to fuse or break. This particular resistance prevents sparking of the studs, and allows of the motor starting on all loads on the first stud. Slow motion gear is not necessary, and we understand that the starters will stand up to heavy service.

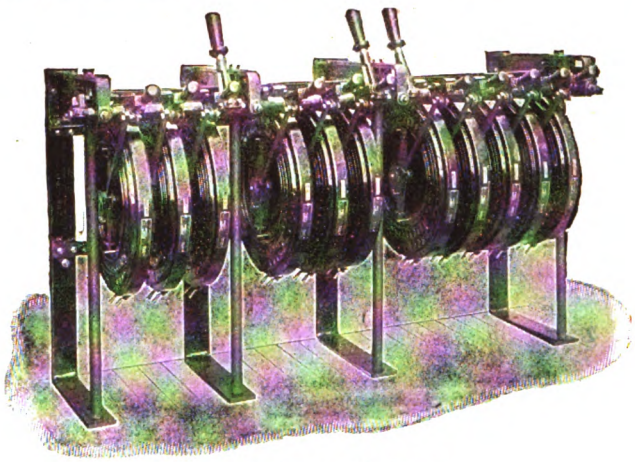
STAGE LIGHTING.

We have had occasion from time to time to comment upon the developments in the construction of electrical apparatus for the general control of theatre lighting. In this sphere of illumination the "dimmer" now occupies a position of considerable prominence, and its relation to the lighting equipment of a theatre is an extremely important one. For many years the liquid dimmer was installed, and there can be no doubt

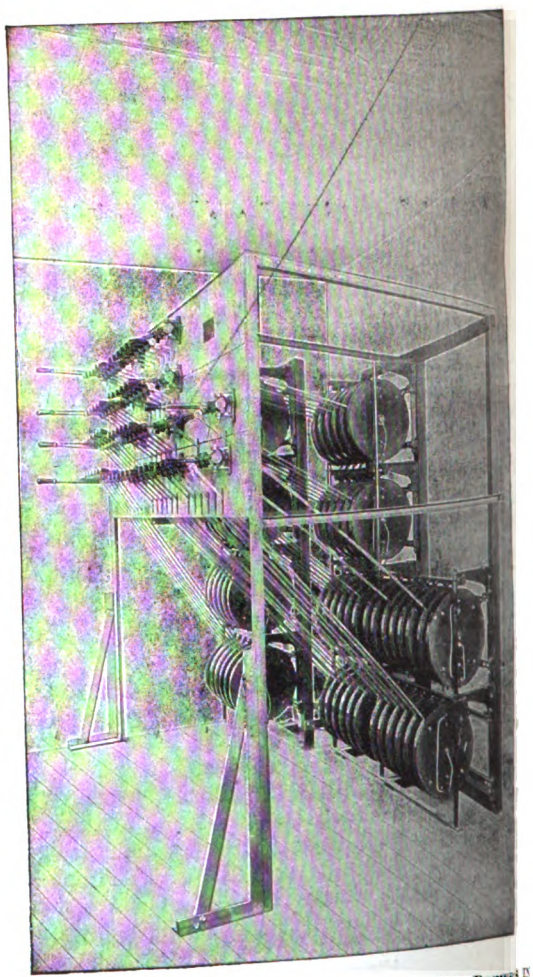


GROUP OF IGRANIC DIMMERS.

that it presented a fairly satisfactory solution of the problem. Long experience, however, has brought out its principal defects and emphasised the necessity for improvement. Judging by the literature issued by the Adams Mfg. Co. on this subject in general and the design in construction of the Igranic metallic dimmer in particular sufficient progress has been made to justify the close attention of theatre managers to this type of resistance. The Igranic metallic dimmer is of the radial-contact type with the resistances embedded in fireproof cement in recesses in a circular iron frame. The resistances occupy a position concentric with the radial contacts. It is

LEVER BY WHICH SINGLE DIMMER IS COUPLED TO A GROUP FOR FULL STAGE EFFECTS.

only necessary to attach a lever to the moving contact arm and to place this lever in the most suitable position for operating in order to provide a complete self-contained dimmer. A number of the resistances can be grouped together, and it is possible to so arrange the operating levers that they can be moved individually or collectively in any desired number of groups. The resistances may be placed in any desired position with respect to the operating levers, the connection between the lever and the moving switch being then a purely mechanical one. In the old pattern of multi-contact switch the switch being placed on a switchboard and connected by cables to resistance frames placed high on the wall there was considerable risk of fire or of troubles with the connections. With the Igranic dimmer this risk appears to be entirely removed, because the connections between the radial contacts and the



VIEW SHOWING METHOD OF OPERATING A NUMBER OF DIMMERS IN A METAL SUPPORTING FRAME.

various points of the embedded resistances form part and parcel of the dimmer unit. It is only necessary to bring two leads of the circuit upon which the dimming is to be done. The illustrations accompanying this short notice will explain

how this useful and compact dimmer can be made up to suit the requirements of various locations.

Dimmers are supplied for two or three wire circuit 110 or 120 volts. They are standardised for a maximum current of 100 amperes on the first step and 25 amperes on the last step, this being the largest size made for 110-volt circuits. For 220 volts the current is halved. The pamphlet which we have already mentioned has been prepared with a view to giving a volume of information on the use of these dimmers. We would recommend interested electrical contractors and consulting engineers to obtain a copy, and we understand that this will be forwarded on request.

We are informed by the Adams Mfg. Co., who are the makers of this interesting device, that it has been fitted to the Little Theatre, Adelphi, London, W.C.

"ONEWATT" LANTERNS.

The improved type of high efficiency drawn tungsten lamps which have been on the market for some time under the trade name of "Onewatt" are, we understand, making considerable progress. Messrs. Siemens Bros. Dynamo Works appreciate the importance of the use of these lamps in properly designed lanterns. They have therefore brought out a type of fitting, which will be known as the "Bradford" lantern, and this is being made in various sizes. We give an illustration of one of these herewith. The smallest size is suitable for 50 or 100-watt bell-shaped or spherical lamps. The lantern will also accommodate 200-watt lamps, and the largest size will take lamps of from 300 to 1,000 watts. The lantern body is of zinc with a large dished white enamelled reflector. Clamped under this

THE "BRADFORD" LANTERN.

is a fluted air globe. The lantern should be in demand amongst tradesmen for outside shop lighting, and also amongst central station engineers for street lighting. The overall dimensions of the size illustrated are 15 in. by 15 in. Shopkeepers should especially welcome a fitting of this kind because it replaces the small arc lamp, gives no trouble, does not need trimming and will give more light without risk than a "gas arc."

THE ELECTRICIAN COMMERCIAL AND INDUSTRIAL SUPPLEMENT.

C. & I. Supplement No. 96.] AUGUST 4, 1911. [Gratis to Subscribers.

A MOTOR-OPERATED BALING PRESS.

Electricity is now being adapted for working baling presses. Hitherto hydraulics have practically held the field against all comers as the source of power for such presses. In places where the water pressure cannot be obtained from a central source, the use of hydraulic pressure carries with it the necessity of installing pumps or accumulators with their attendant heavy foundations and excavations. Now electricity is being introduced for this class of apparatus and a new type of baling press operated by an electric motor has been designed and constructed. In the electric press, according to the "Electrical Review and Western Electrician," the moving table is swung from the press head by means of steel-wire ropes, which are arranged in sets of four, two at each end of the table, which is equivalent to lifting at the four corners. The end of each rope is secured to the press head and passes round a number of sheaves, whereby a purchase is obtained; the free ends of the four ropes being wound simultaneously on to drums, which are directly driven from a reversible motor, through suitable reducing gear. In the hydraulic system the press head is attached to the cylinder by corner tie rods of the requisite combined sectional area to withstand the full pressure exerted by the ram. In the electric press no such stresses are involved on the corner pillars, which merely support the press head and the machinery contained thereon; consequently they only act as guides for the moving table on which the bale, or the material to be compressed is placed. This table is forcibly pulled up by means of the steel ropes, which divide the load equally. Both this table and the press head are therefore of similar design and are simply beams or girders supported at the ends and loaded in some symmetrical manner, distributed about the centre line.

A series-wound motor is used in which the ratio of speed from no load to full load is at least three to one; this ratio can if necessary be made greater by employing a diverter resistance in parallel with the fields, or by using a double commutator motor with a series-parallel control. The motor is run in one direction to lift and in the reverse direction to lower the table, an important feature of the new electric press being that the sheaves should be limited to such a number that the efficiency of the wire-rope blocks may be more than 50 per cent. when lifting the empty table, under which circumstances the table will run down by its own weight when the motor is reversed and the ropes are paid off the drums.

As the material or bale is compressed the motor current gradually increases to a maximum corresponding to the total pressure required. Duplicate circuit-breakers operate to open the circuit at the point of maximum load, and an automatic brake on the armature spindle sustains the table without further expenditure of electrical energy.

The size of the motor is determined by the maximum specified pressure and the final speed of the table at that point; thus in a 100-ton press having a final speed of 3 in. per minute, the work performed would be at the rate of 50,000 ft. pounds per minute, or say 1·5 H.P.; the brake-horse-power of the motor being about 50 per cent. greater than this figure to allow for losses due to friction, as is usual in the design of electric cranes. The motor may, however, be more highly rated than for steady load, for not only does it run for a very short period, but the average of the load-curve is only 25 per cent. of its maximum. Very little resistance is offered during the greater portion of the compression, which simply means expelling air from the folds of the material to be compressed.

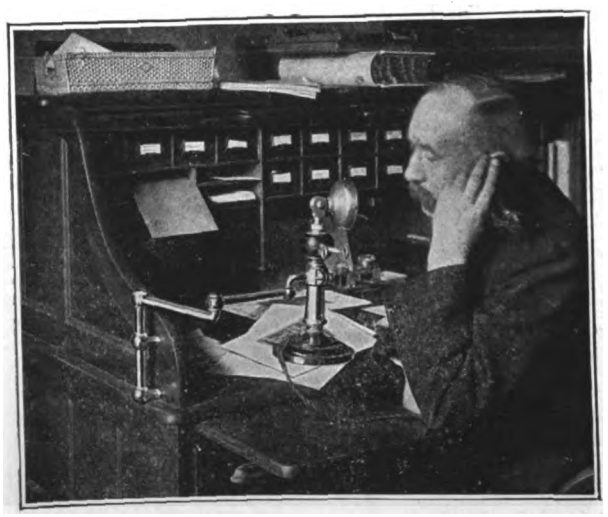
THE HELPTOPHONE.

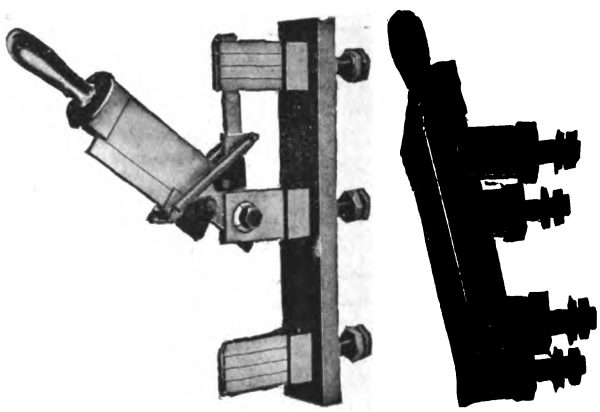
The busy commercial man expends a considerable amount of energy daily in lifting down his telephone receiver and holding the transmitter with its heavy base up to his mouth. Since the Post Office abandoned the hand combination instrument for the desk type with separate receiver and transmitter the commercial telephone has become a much more cumbersome instrument to use. A man who handles upwards of 100 calls during the day should take advantage of the neat device shown in the accompanying illustration. It depicts the Simplex "Helptophone," and it will be noticed that it consists of a simple bracket with three hinged extension arms to the outermost of which the telephone transmitter and its base are clamped. A handy device of this kind will save a lot of time and labour and keep the busy man's telephone at his elbow and in such a position as to be clear of the papers on his desk. The instrument is made in a variety of sizes having different lengths of extension. It is extremely moderate in price. The smallest instrument extends to 18 in. and the largest to 23 in. We understand that it can be supplied for use with inter-communication instruments as well as for those of the N.T.C. Simplex Conduits will supply full particulars and prices.



THE HELPTOPHONE IN USE.

G.E.C. KNIFE SWITCHES.

The knife switch is a comparatively common piece of electrical apparatus, and on this account the details of its design and construction are apt to be overlooked. The feeling is probably that when a knife switch is required any cheap and nasty type can be made use of. This is, of course, a big mistake, because the knife switch, particularly one of the heavy current pattern, has as important a function in the circuit as a more expensive piece of apparatus. The General Electric Co. have sent us particulars of a standard line of their knife switches, all of which we understand are manufactured at their Witton works. The switches have been generously designed and are of ample dimensions. A low current density has been worked to. The makers state that at no part of the switch does it exceed 1,000 amperes per square inch for high conductivity copper and 60 amperes per square inch in the contact clips. On the score of surface density the switches appear to have a large margin to spare. In fact, the makers are so confident upon this score that they claim that the switches can be overloaded as much as 50 per cent. without dangerous heating, and much higher for short periods such as emergency overloads. The usual type of flipper blades are fitted to give the requisite quick break. In the fitting of these blades to the contact blade a steel stamping is employed and the main blade is bushed with a steel bush for the hinge pin. At the handle end the main blades are fitted with solid steel blocks upon which the handle is screwed. In switches of the change-over type shaped steel springs are provided, which are fixed to the side of the hinge contact and act on the rounded end of the flipper blade pivot pin. The switches are stocked single, double and triple pole and can be supplied for front or back connection. The above illustrations explain the general details.



S.P. CHANGE-OVER SWITCH. D.P. SWITCH.

AN ELECTRIC CYCLE.

We receive, repeatedly, inquiries from all parts of the world for the latest electric cycle, the request usually being for one fitted with "Edison's battery." We gather from our American contemporary the "Electrical World" that a satisfactory

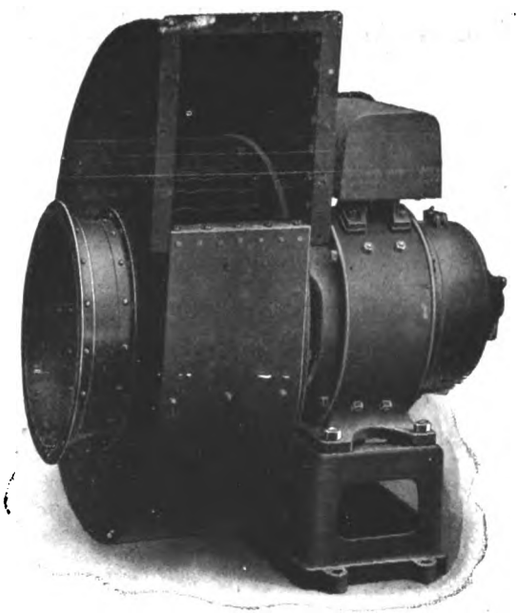
Economy. Efficiency.



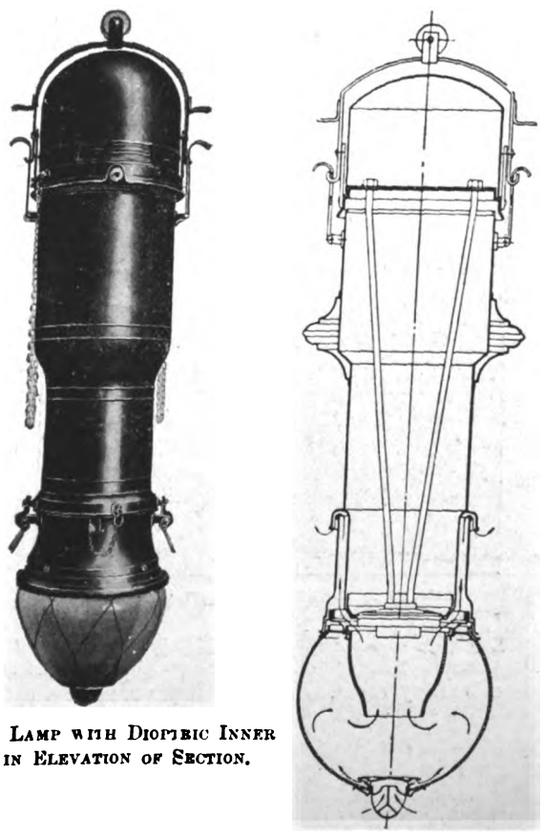
The Electric & Ordnance Accessories Co., Ltd.,
Proprietors: VICKERS LIMITED.
Aston, Birmingham.

electric vehicle has been invented by a Mr. F. E. Hatch, 85, Horton-avenue, Detroit, Mich. (We print the address in full for the benefit of likely correspondents). An illustration of the machine is given in the journal mentioned and it shows a large battery underhung in the frame between the two wheels and motor immediately below the saddle with chain drive to the back wheel. The battery is of six cells and the motor operates at 12 volts giving speeds of 4, 15 and 35 miles per hour. The battery is said to have a radius of 100 miles on asphalt or tarred roads in town areas and 75 miles over country "give and take" roads. The vehicle weighs 200 lb. An Edison Exide or any standard battery can be used. The machine has a 51 in. wheel base, and the motor is fitted with ball bearings.

A standard British Triumph 3½ H.P. motor cycle weighs about 150 lb. and has a range of 120 miles with one filling of petrol, also a maximum speed of about 45 to 50 miles per hour. If fitted with magneto ignition it will start up at any time, so that the advantage of the electric vehicle is practically nil in comparison.

THE NEW EXCELLO LIST.

The flame arc lamp movement in its early stages probably received its chief impetus from the Excello lamp, and there are many important installations of this lamp in all parts of the world. In spite of its popularity the makers are constantly improving the lamp in detail, and we gather from the latest list that the 1911-2 Excello has points of interest and novelty to distinguish it from its predecessors, while all its specially unique features are retained. The list to which we refer (7,023) is just issued, and our readers who are in need of information regarding the latest Excello should obtain a copy. The deposit-free cover of course still figures prominently in the list and also the storm-proof ash tray. It should be noted that the old pattern lamps can be converted to deposit-free at a comparatively small cost, considering the advantages in light efficiency obtained.



EXCELLO LAMP WITH DIOPTRIC INNER GLOBE, IN ELEVATION OF SECTION.

For the illumination of large areas, streets, wharves, dock-sides, public squares, &c., the flame arc lamp is not so suitable

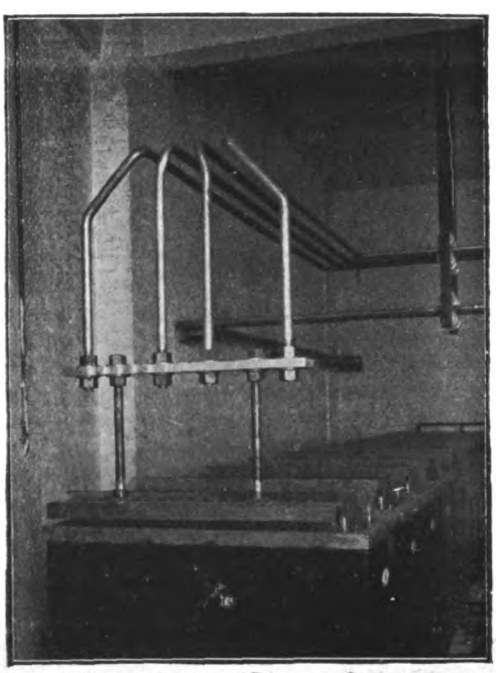
136, GOWER St., & 24, Gower Place, LONDON, W.C.

as the open arc, because the downward illumination of the latter is too intense. By the use of a dioptric inner globe the rays of light from the arc can be bent in a more horizontal direction and the distribution of light over a wider area can be effected by this simple means. The angle at which the maximum of light is obtained by the use of the dioptric globe is 20 to 30 degrees below the horizontal. The globe itself is made up of a number of prism rings of different angles, and by reason of its position inside the outer globe it remains free from the deposits of the arc. In a general scheme of exterior illumination it means that by the use of the dioptric inner globe a smaller number of lamps is needed than would be the case if the globe was not introduced. The Excello arc lamp is, of course, suitable for a.c. and d.c. circuits and can be burned single or in series according to circumstances. Another feature of the list is a dimension sheet of the different kinds of globes used with Excello lamps.

ALUMINIUM BATTERY CONNECTIONS.

The value of aluminium conductors has been demonstrated recently, principally in connection with low-tension heavy-current networks, &c. In the battery room this class of conductor has been proved to be exceptionally useful by reason

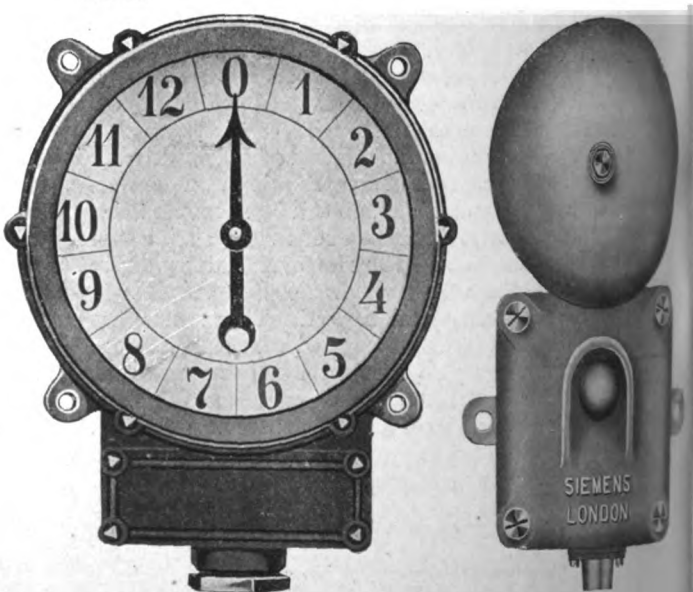


VIEW OF ALUMINIUM BATTERY CONNECTIONS.

of its light weight and acid resisting properties. It is a difficult and expensive matter to carry heavy copper rods and bars about a battery room, but aluminium presents a convenient solution of the problem. The British Aluminium Co. has recently installed a quantity of 1¼ in. diameter aluminium round rod in the battery room of the Westminster Electric Supply Co.'s new station, Horseferry-road, Westminster. In the adjoining illustration we show how easily the rod can be bent to suit the angles of the battery room and the position of the terminals. The particular battery on which these aluminium conductors were used is of the standard type, with sweating sockets for solid copper rods. It was not thought advisable to alter this connection, so the copper rods were cut off at a convenient height above the end cell and joined to an aluminium bridge piece. Into this bridge piece the connecting aluminium rods have been bolted. The rods themselves are supported by reel insulators placed in hangers suspended from the roof. The rods are taken the full length of the building to the switchboard. All the joints were made by butt welding, so that no solder or foreign metal was introduced.

BELL SIGNAL INDICATORS.

Where electric bells are employed to give important signals it is advisable and often necessary to have some visual indication of the signals given. Siemens bell indicator consists of a dial instrument which indicates the number of bell strokes given, and is particularly applicable for shaft winding or haulage in mines. It comprises an electromagnet which operates an armature, actuating a pointer through one section of the dial for each ring of the bell, so that the number of rings received is recorded by the pointer. It is provided with a releasing mechanism to set the pointer back to zero. This can be done either by hand at the instrument by means of a lever provided, or electrically by a press button switch in the engine room. This switch may also be so arranged that it is automatically operated by the engine. The indicator can be applied to any existing bell signalling apparatus without any alteration to the latter.



BELL INDICATOR AND BELL WITH PUSH KEY.

Two bells with a dial indicator are provided in the engine room, the latter indicating the number of strokes on the bells, thus forming a visual indication of the order received. A bell and two

press switches are also provided at the pit bank, and a bell and press switch at the pit level, which enable the usual order of bell signals to be used.

The following description of working the signals is only taken as an example to illustrate how the apparatus may be used. The procedure may be varied to suit the requirements in each particular case. For instance, if men are to descend the shaft, the banksman gives three rings on his own bell and that at the pit level by pressing one of the switches at the pit bank. To this signal the onsetter at the level replies, before men enter the cage, by giving the bell at the pit bank three rings; at the same time one of the bells in the engine room will ring three times, and the indicator moves forward one step for each ring and will stand at 3. When the onsetter's cage is ready to ascend he signals the banksman and engine man one, the pointer on the indicator moving forward to 4. To start the descending cage the banksman now signals to the engine man by pressing the second switch and ringing the second bell in the engine room once. The indicator pointer moving to the engine man knows that the cage is ready to descend and proceeds accordingly, at the same time putting the pointer back to zero by means of the press switch. This last operation can also be effected by a release switch actuated by the engine, so that it is impossible for the engine to be moved and the old order to remain on the dial. The divisions on the dial allow various extra orders to be used up to 12 bell strokes. Whenever a signal is sent from the level or pit bank, the bell at either of these places rings, thus confirming that the signal has been received correctly. The bell signal system with indicator can also be adapted for mines having two or more levels.

FLAME ARC WITH UNIQUE TWO YEARS' WARRANTY

A NEW E.C.C. MOTOR.

The Electric Construction Co. have just introduced a new direct-current motor, which is designed to meet the demand for a cheap yet thoroughly reliable low-power machine. Its construction embodies various new features—notably a radial commutator—which reduces manufacturing costs, and at the same time sacrifices nothing to efficiency, mechanical strength or general reliability. The temperature rise of the "S V P" motor does not exceed 70°F., after six hours' run at full load, and it has an overload capacity of 25 per cent. for two hours and 50 per cent. momentarily. The face of the commutator is in the vertical plane. Each of the two brushes is held against the commutator by a small spiral spring, adjustable for pressure by means of a milled-head vulcanite screw. Some of the advantages derived from the adoption of the vertical commutator may be stated briefly. (1) Cost of production is reduced. (2) The brushes are accessible from the outside of the frame. Adjustment or replacement of the brushes is much easier than in an ordinary open machine, although the "S V P" motor is of the protected type. (3) Smooth running is assured, and the danger of high bars or of the commutator getting out of truth is remote. (4) As the commutator surface is flat, practically no bedding of the brushes is required. (5) The overall length of the motor is reduced. The "S V P" motor is at present offered for the following outputs: ¾ B.H.P. at 1,000 revs. per min., 1 B.H.P. at 1,400 revs. per min., 1½ B.H.P. at 2,000 revs. per min. Interested readers should apply for fuller particulars and prices either to the head offices of the company at Dashwood House, London, E.C., or the works, Wolverhampton.

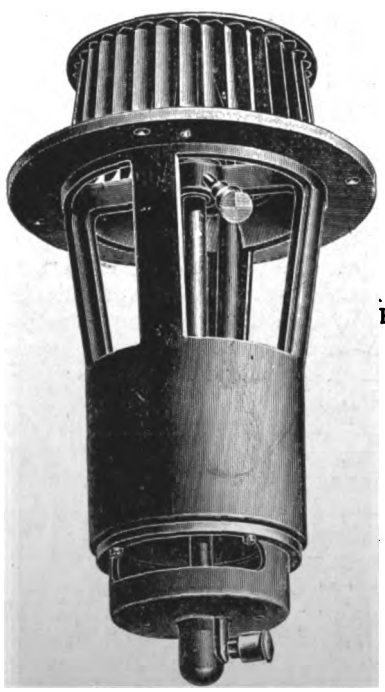
STERLING TELEPHONES
The Sterling Telephone & Electric Co., Ltd., 200, Upper Thames Street, London, E.C. Works: Dagenham, Essex.

MINING TELEPHONES.

Electric bells have been installed for many years in mines and collieries, and gradually the telephone has been brought into play and is replacing or supplementing in many districts the original bell system. Messrs. Haslam & Schontheil of Cardiff are issuing particulars of a line of telephone instruments which are quite suitable for use in mines. The novelty of the instrument consists in the use of hearing and speaking flexible tubes which are brought out from the case of the instrument by a special elbow. At the extremity of these tubes and inside the cast-iron case are the transmitter and receiver proper. This is an arrangement which dispenses with outside flexible cords and confines the whole of the electrical connections to the fixed case in which they are permanently enclosed. Aluminium mouth-and-ear pieces are attached to the "hand-com" fitting at the outer end of the flexible tubes. A magneto call bell is placed in a separate compartment at the bottom of the case. The instrument is strongly recommended for coal mines, steel works and engine rooms, or in fact any position where risk in handling is likely to be met with and where it is essential to use a water, dust and gas-tight enclosing case.

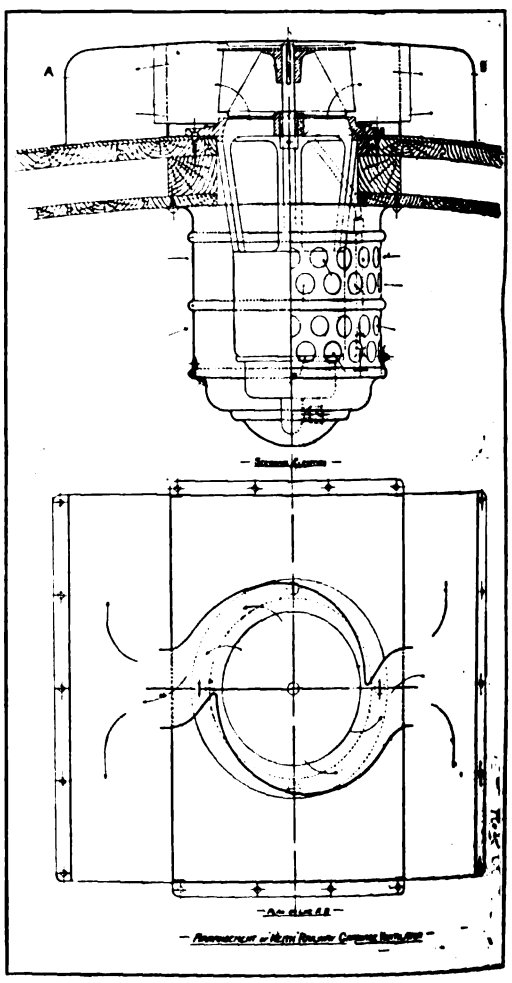
RAILWAY SALOON VENTILATION.

The supply of fresh air to the average dining saloon on railway trains is not altogether an easy problem. The use of bracket fans at each end of the saloon is certainly no solution of the problem, because the fans simply blow the vitiated air backwards and forwards, and as a rule there is some "crusty"



KEITH RAILWAY SALOON FAN.

passenger who objects to the breeze because it is a "draught." In both summer and winter the air in these saloons is generally at too high a temperature, and this fact is simply attributable to faulty ventilation. Messrs. James Keith & Blackman have developed a form of carriage ventilator which certainly tackles the problem on a more reasonable basis. A small Keith fan of the centrifugal type and 5 in. diameter is directly connected to a vertical spindle electric motor. The motor is placed inside the roof of the saloon and drives the fan wheel, which is outside, through an extension of the motor shafting. The wheel runs in a specially designed cowl and discharges into two channels which are constructed so that there is no back draught,



SECTION AND PLAN OF KEITH RAILWAY FAN.

and it is impossible for flying cinders from the engine to enter the wheel casing when the fan is out of use. Both fan and wheel are self-contained, and can be dropped through a port-hole in the roof, a flange under the fan wheel taking the weight and only needing fixing by a few screws. The motor itself is covered by an ornamental ventilated casing, which is supported inside the ceiling of the saloon. The illustrations herewith will explain the design of the ventilator.

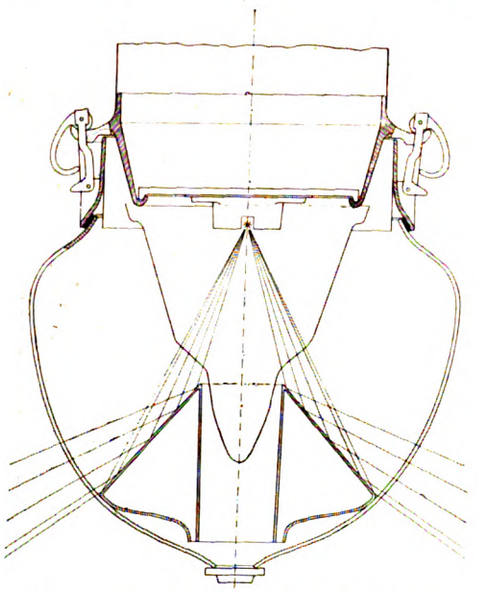
MULTAX ARC LAMPS.

The makers of this lamp, the Globe Electric Company, have just issued a brochure describing the latest pattern in which the burning hours have been increased 150 per cent. without adding to the length of the lamp. Our readers will doubtless remember that patent bridge-core carbons are used in conjunction with a special method of enclosure of the arc. The latter comprises a replaceable fire-resisting inner globe which is fitted to the lamp in such a way that the fumes from the carbons are carried away at the top of the globe case and do not enter the mechanism of the lamp. The sectional illustration herewith will explain this arrangement. It also shows the patent light distributor which bends the light rays considerably towards the horizontal. The deflector is described in the list as a hollow glass ring of triangular section, the inside surface of the hypotenuse being silvered. It is placed in the bottom of the globe and its slope is so proportioned that the rays from the arc fall on it at the proper angle required to bend them in a horizontal direction. The fact that the silvering is done on the inside of the glass ensures a constant brilliance for the reflecting surface quite irrespective of the cleaning of the globe.



View of Multax Distributing Reflector.

The Multax lamp is offered in two patterns, one for 20 to 25 and the other for 26 to 40 burning hours. The first-mentioned lamp is only 33 in. in overall length and is recommended by the makers for shops and public buildings. The lamp is made for direct-current and alternating-current circuits and the Globe Electric Co., Farringdon-avenue, London, E.C., will be glad to send fuller particulars on request.

A NOVEL COVER.

In this country we are not privileged to utilise the front covers of our technical periodicals for other than advertising matter. The "Canadian Electrical News" established a useful precedent in one of its recent issues by reproducing on the front cover a highly original design by an equally original artist. We reproduce the design on a small scale herewith. It is self-explanatory and will bear examination in detail. We commend it specially to the notice of students of wireless telegraphy, as possibly they may evolve some new application of etheric wave systems from it.

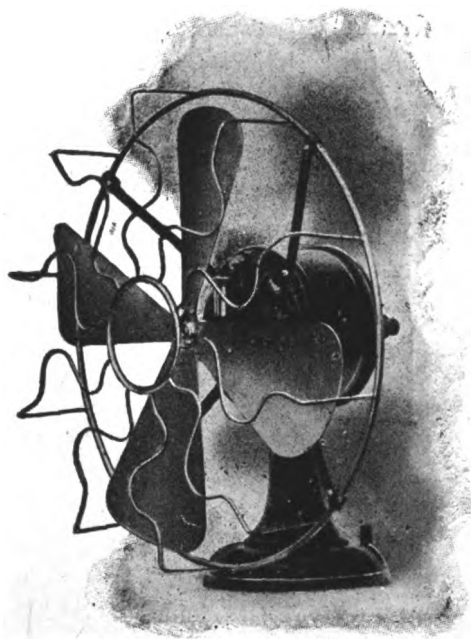
SIMPLEX FANS AND SMALL MOTORS.

In the new Simplex fan list will be found a range of electric cooling devices to suit all tastes and requirements. The now familiar types of fan—desk, bracket, ceiling and porthole—are well represented. Swivelling bases for fans are also a feature of the list. These have come to the front of recent years and are deservedly popular. It is possible by their use to use



Simplex Desk Fan.

a fan and distribute the breeze about a room or office, the result being somewhat of an economy in fans, because one man in a large office who may be the head of a department can arrange matters that the breeze from his single fan can be shared by the other members of the staff. In the Simplex fan list is also a full account of the Simplex small motors. Among these we notice a polyphase motor, the driving of looms and the other small power machines in textile factories. This motor is fitted with the balance cradle suspension and balanced spring tension adjustment for tightening the belt automatically.

THE ELECTRICIAN COMMERCIAL AND INDUSTRIAL SUPPLEMENT.

C. & I. Supplement No. 97.] AUGUST 11, 1911. [Gratis to Subscribers.

CAN IT BE POSSIBLE?

In their competition with electric light the advocates of gas have put up some remarkable performances. The records of the controversy show the display of a greater amount of zeal on the part of the champions of gas as compared with those of electricity. In the case of gas the realisation of the knowledge of the ultimate result of the struggle must be somewhat fateful like the classic sword of Damocles over the heads of the contestants. The time appointed for the falling of that sword is not a matter for discussion at the moment. The development of the struggle between the two illuminants, particularly in the past 12 months, has witnessed a consistent advance of electricity side by side with the adoption of tactics by the gas adherents which can only be attributed to the promptings of despair.

In the present year of grace electricity has taken advantage of the great opportunity presented by the Coronation. In spite of all the shufflings of the gas partisans, they have emerged from the competition in the decorative illuminations as the laughing-stock of the entire country. Our rivals are unfortunately unable to profit by this rebuff—they have simply to take it lying down.

Not content with administering a decided setback to gas at the Coronation, the electrical industry is having the audacity to hold an Electrical Exhibition at Olympia in the autumn of this year. This exhibition will centre public interest in electricity and will undoubtedly give a great impetus to the wider utilisation of electrical energy for lighting, heating and power. Of these three we confidently anticipate that lighting and the sale of metal lamps will receive an extraordinary fillip. We have ventured on previous occasions to suggest the possibility of a reduction in the price of metal lamps for this exhibition. While we look forward to it with confidence the gas interests cannot but regard it with the utmost dread. We appear to hold several trump cards in the game we are playing. Not only have we a considerable amount in hand in regard to the price of electrical energy for lighting purposes (indeed there are some engineers of large stations who hope that the lighting load will be something of a by-product), but also we have the tremendous advantage of being able to bring down, with their increased use, the cost of all electricity-consuming devices, be they lamps, motors, heaters, &c. With gas, on the other hand, there appears to be only one weapon left, that is, the price of the commodity, for it is difficult to conceive that the cost of gas-consuming devices can be reduced very much lower than it is at present.

Reduced to this extremity the gas industry is occupying itself in the attempt to discover some means of stemming the tide in favour of electricity. We hear rumours that efforts are being made to revive the gas-driven dynamo for electric-light consumers, and particularly the large consumer, who is a profitable adjunct to the electric light mains. We understand that a scheme is on foot in one of the large provincial towns to put in gas plant and supply cheap gas at a rate which will make the cost of the electricity generated 1d. per unit. The consumer is to be relieved of all capital charges and the maintenance of the plant. A nominal charge per horse-power per annum only will be made, and while the gas suppliers will make what profit they can out of the transaction the electricity consumer, who will then become their customer, will still retain the advantages which originally influenced him in adopting electric lighting. This is a crafty manœuvre and does not deserve to succeed. There are even suggestions that the town supply can be used as a standby. If this is proposed, the station engineer has the obvious rejoinder to fixing the maximum charge under the Act for this class of service. Faced with the possibility of paying

for energy at the rate of £8 per kilowatt per annum, and with a shaky gas engine in the cellar, the electricity consumer would doubtless feel that he had dropped the bone in grasping for the shadow. We invite our readers to co-operate in the supply of particulars from their districts as to what is being done both by the gas engine makers and gas suppliers towards the placing of a scheme of this kind on its legs. For the moment we are content to repeat the question, Can it be possible?

EFFICIENT GRINDING.

Engineers have made use of grindstones ever since the cradle days of the industry, but the most sanguine of the pioneers of grinding machinery would not have prophesied the evolution of present methods from so simple a beginning. Modern abrasives are sufficiently hard to apply to the hardest metals and innumerable commercial processes are given a remarkably high degree of accuracy simply on account of the grinding methods introduced. Some idea of the diversity of these methods can be gathered from a list just published by B. R. Rowland & Co., of Reddish, who have made a study of abrasives and their practical applications for over a quarter of a century. They offer a number of different kinds of abrasives for different purposes. These include corundum which is the hardest substance known to science, excepting the diamond, crystal Canadian corundum, which is a cutting material, and does not rub, burn, or glaze; it is recommended for steel tools because it will not draw the temper. This last-named abrasive owes its special properties to the absence of chemically combined water and lime and to its crystallisation. Then there is carbo-corundum which is produced by an electrochemical process; this is infusible at the highest temperatures and is insoluble in all liquids. It is more brittle than crystal corundum and is recommended for certain special purposes.

Messrs. Rowland & Co., in addition to making abrasives, are also manufacturers of grinding machines. They have a special method of mounting for grinding wheels, the feature of which is the fitting of one plate over the boss of the other and the recessing of all bolt heads. The inner faces of the plates are dovetailed and fit the wheels in such a manner that wholly eliminate the risk of bursting. Of the grinding machines we can say that they are offered in many types and sizes. A special pattern is one for twist drill grinding. This will take drills up to 2½ in. diameter and is fitted with belt-driven centrifugal water pumps and a smaller wheel for thinning off the drill points. All patterns of grinders can be arranged for belt or motor drive. A large fully illustrated catalogue has been prepared of all the machines made by this company and a copy will be forwarded to interested inquirers.

SIMPLEX NEW FITTINGS.

A supplementary fittings list has just been issued by Simplex Conduits, and it will be found to contain a great variety of new designs. The pages of the list are devoted, in pairs, to the different styles or periods which the fittings represent. The Adam, Georgian, Dutch and modern are represented, the concluding pair of pages dealing with holophane fittings. The designs shown are tasteful and artistic. On the score of price practically every pocket is catered for. The holophane fittings especially are very reasonable but at the same time are well selected and admirably suitable for flats and small households. A novelty among the holophanes is a dining-room pendant, hung from an ornamental ceiling fitting by three chains, there being a reflector bowl at the lower end surrounded by a large silk shade. The holophane table standards are also very pretty.

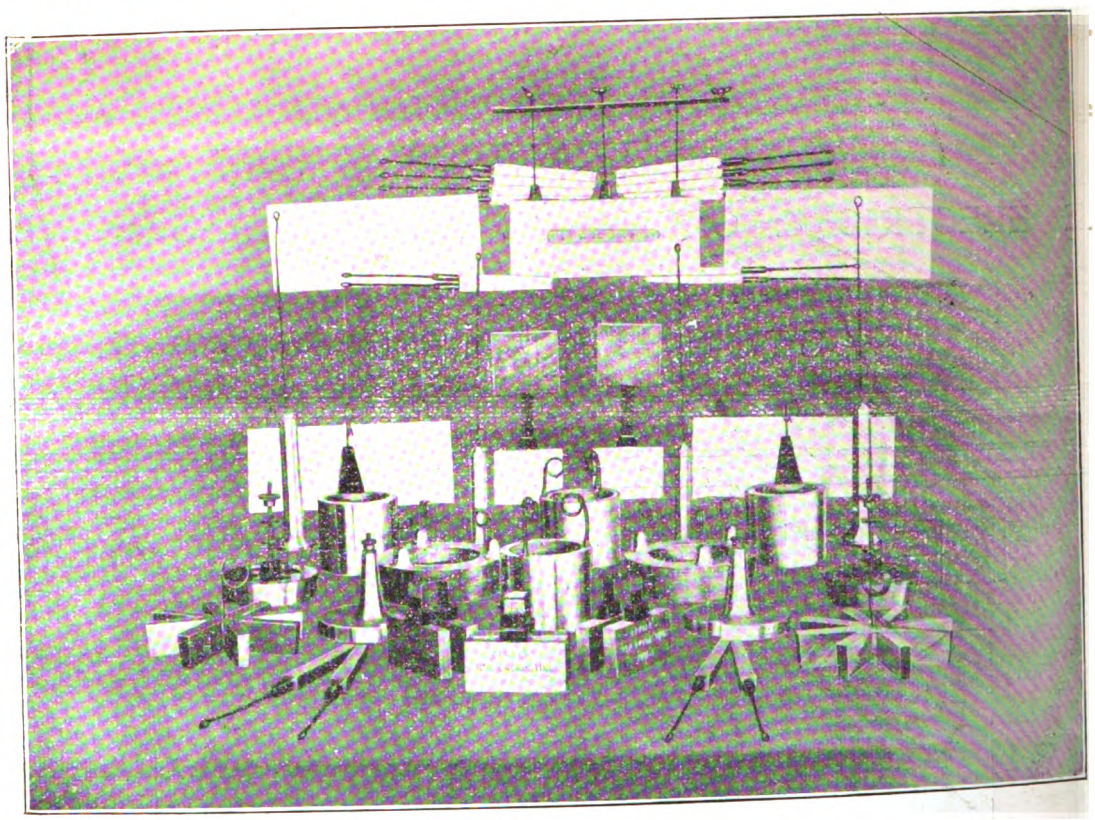
BAMBER NON-ENCRUSTING ZINCS.

Most of the commercial primary batteries in use to-day are fitted with zinc as one of the elements. This metal is gradually eaten away as the battery is used and must be replaced at intervals which vary with the amount of work done by the battery. Primary batteries are employed largely on railways for telegraph and track circuits. It is of the utmost importance that the zincs used in these batteries do not become encrusted as the zinc is eaten away. If this takes place there is a considerable reduction in the life of the battery due to local action; the efficiency of the battery is also impaired. For many years past the Eyre Smelting Co. have produced, by a special process, a form of non-encrusting zinc for all classes of primary batteries. These are known as Bamber zincs, and it is claimed for them that they are free from encrustation and local action, they ensure a full and constant supply of current, that they have more than double the life of ordinary zinc, and that they require practically no attention. These claims are certainly not exaggerated, because they are amply confirmed by the reports of actual users of batteries fitted with these special zincs. These reports emanate from railway companies both at home and abroad, electric clock companies and consulting engineers. Tests conducted by the National Physical Laboratory also are conclusive in support of the claims of the makers. One of the latter tests is worth quoting in detail.

"Two simple voltaic cells, with copper plates, and with zinc rods (in one cell a 'Bamber' zinc and in the other an ordinary amalgamated zinc), the sulphuric acid having a specific gravity of 1·074, were connected across a constant resistance of 1 ohm. The discharge was continued for 49 hours, at the end of which time the ordinary zinc rod was gassing violently.



Group of Bamber Non-encrusting Zincs.

"The following figures show at a glance the result of the above test:—

"'Bamber' zinc: 11·7 grammes zinc consumption.
0·6 gramme loss due to local action.

"Ordinary zinc: 26·5 grammes zinc consumption.
10·1 grammes loss due to local action.

"The loss due to local action in the case of the ordinary zinc rod was, therefore, very nearly 17 times that of the 'Bamber' zinc; further, it will be seen that the zinc consumption in this 'Bamber' zinc very closely approximated to the theoretical consumption figure.

"It should be borne in mind that, whilst at the end of this test the ordinary zinc is described as 'gassing violently' and, it is further stated, that the 'protective surface was apparently disintegrated,' no gassing is mentioned for the 'Bamber' zinc, which is described as being 'pitted somewhat irregularly.' It is stated that the main action on the 'Bamber' zinc had apparently taken place at the corners and at the top level of the acid. This latter emphasises the importance of having the largest section at the top of the zinc. In view of this and that the loss of zinc on the 'Bamber' zinc up to the end of the test was only about 13 per cent. by weight, we may claim that the useful life of the 'Bamber' was no means at an end."

We take the foregoing illustration from a list just issued by the makers and sent to us by their sole London agents, Alan S. King & Co., 28, Victoria-street, Westminster, S.W.

IFS AND QUERIES.

Has the Chairman of the N.E.M.A. melted himself out of the snowdrift yet ?

If there were a society for the protection of electrical salesmen.

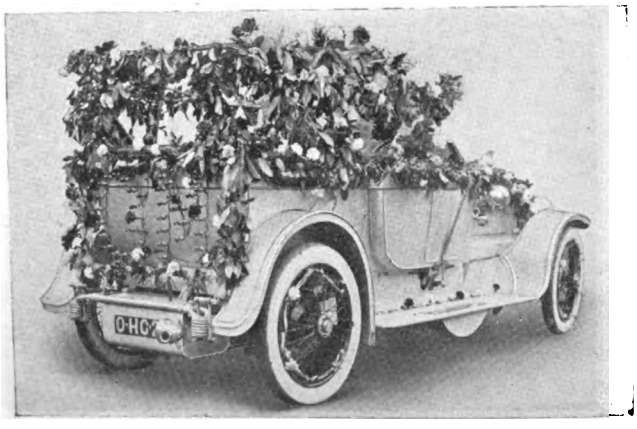
ANOTHER USE FOR OSRAMS.

One of the interesting instances of electrical illumination on the occasion of the recent Coronation Festivities was that of a 23 H.P. six-cylinder "Daimler" Car, belonging to Mr. G. F. Heath, of Birmingham. For some days during the period in question this car, which is known locally as "Silvery Silence," attracted considerable attention in the Midlands on account of



MOTOR CAR ILLUMINATED WITH OSRAM LAMPS.

its elaborate scheme of decorative illumination, the entire effect being produced by means of 400 Osram lamps. Osrams were also fixed to the wheels of the car and revolving with them greatly added to the artistic effect. Such a test speaks well for the strength of the Osram filament, and if they will stand the "jolts" and "jars" of rough roads (to which the wheels of any car must be subjected) they are more than especially suitable for the wear and tear of ordinary everyday use.

ELECTRIC POWER IN QUARRYING.

There is a field of industry in this country in which, as far as we are able to gather, electric power has made but little headway. This is in the quarrying business, and the lack of users of electrical energy in this particular province is probably due to the distance of quarries from sources of supply. With large concerns, however, there should be sufficient justification for the installation of a central plant from which energy can be transmitted and distributed to the various motors. An interesting instance of electric driving on these lines is afforded by the equipment of the Dolese & Shepard Co.'s quarry which is located on the drainage canal of the sanitary district, Chicago. The site of the quarry is within touch of the power supply mains of the Economy Light & Power Co., of Joliet, and a demand of 1,200 kw. is made regularly on this concern. The use of electrical energy was hastened considerably by the fact that a fire destroyed a portion of the works, and in the rebuilding operations it was decided to use electric power. Motors are employed for drilling, loading cars, and conveying, shovelling and crushing. The electric drills in use replaced a number of compressed air drills and they are operated at half the previous cost with an increase of 25 per cent. in the output. The loading cars are supplied with energy from a third rail, and a batch of 25 cars daily handles 6,000 to 8,000 tons of stone, and only two men are required to run the cars as against a large number needed for the original seven steam locomotives. Each car holds 20 tons and runs up a 6 per cent. gradient to a height of 70 ft.

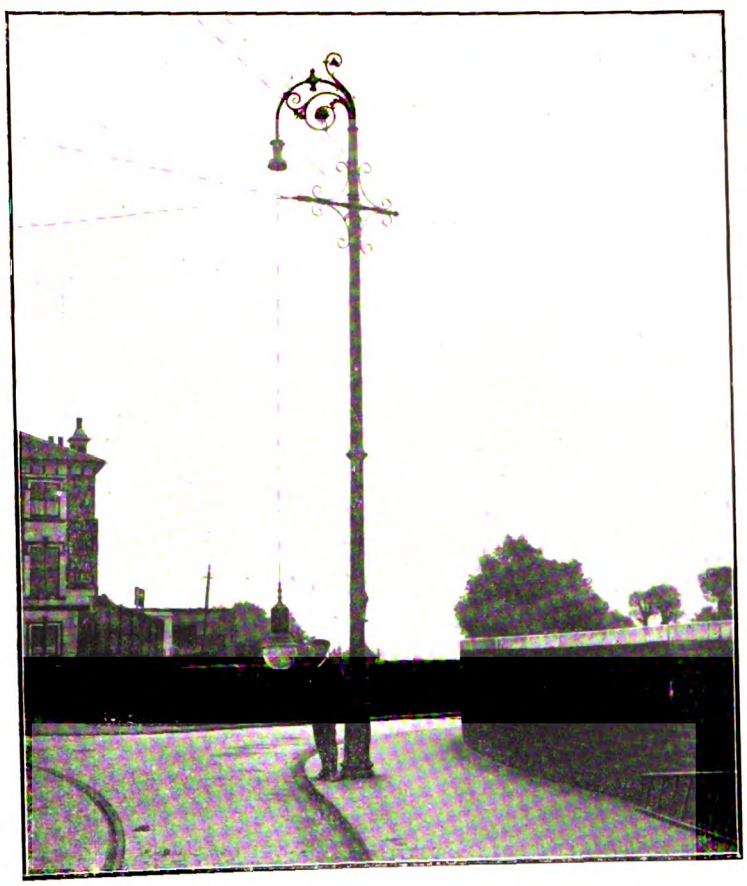
the crusher. The cars are electrically braked on the descent, and the motors are connected to a dead resistance formed of No. 6 Climax wire. The crushers handle 50 tons an hour and rolls are used for reducing below 6 in. in size. In the sub-station are motor generators for conversion of the transmitted energy to direct current, and also transformers for lowering the alternating-current supply to 440 volts.

TANTALUM SHOW CARD COMPETITION.

We are asked by Siemens Bros. Dynamo Works to announce that the number of designs submitted for their show card competition is far in excess of their wildest anticipations. The work of the many competitors is however being gone over as quickly as possible and the selection of the best designs will be announced shortly.

METAL LAMPS AND LOWERING GEARS.

During the past 12 months the metal lamp has made extraordinary progress in street lighting. We have had occasion to record the displacement of arc lamps of the open type either by



METAL LAMP LANTERN AND LOWERING GEAR AT CROYDON. (London Electric Firm).

metal lamp clusters or high candle-power lamps. The development of the metal lamp for street lighting has up till now been principally in the direction of side streets, but since the domain of the arc lamp has been invaded the metal lamp has figured prominently in large thoroughfares, and probably the principal item of interest is the use of lowering gear for the metal lamp lantern which has taken the place of the arc lamp on the same post. Messrs. The London Electric Firm, of Croydon, who are specialists in a patent form of lowering gear having only one part, have introduced these devices for metal lamps in a large number of districts. We illustrate one of the lamp-posts at Croydon fitted with this gear and with the lamp lowered for cleaning and general inspection. The makers claim that the use of this gear for metal lamps is justified because their particular device is extremely simple and inexpensive to instal. It dispenses with the time and labour required for the power waggon which is apt to be dangerous and also impede traffic. It may be remarked that the contact suspension device is of the positive acting weight relieving type, and combined with it is a self-contained winch which is without rachets, pawls, springs or triggers.

ELECTRIC SIGNS FOR CHURCHES.

An American contemporary in discussing the merits and development of the electric sign remarks upon the possibility of its use for churches. Although no instances are quoted it is stated that the electric sign is being used by churches, and is considered in good taste. Now in this country if any such movement were set afoot it would be foredoomed to failure because our national ideas are diametrically opposed to those in vogue "across the stream." We ourselves can see no reason why an electric sign should not be used to direct the stranger from a main to a bye thoroughfare in which a place of worship is situated. The actual fixing to the walls of the church or chapel of an electric sign would we imagine rouse a storm of indignation among the congregations over here. Still there are enterprising ministers of the younger schools of British denominations who would erect a "talking sign" on or near the sacred edifice in which they exercised their pastorate. To put up a sign within the precincts of any sacred building would be rightly looked upon as sacrilege. The school and assembly rooms and church hall may appropriately be used to cry out their presence by means of electric signs.

THE ELECTRICIAN COMMERCIAL AND INDUSTRIAL SUPPLEMENT.

C. & I. Supplement No. 98.] AUGUST 18, 1911. [Gratis to Subscribers.

CAN IT BE POSSIBLE?

A COMMENT FROM THE PROVINCES.

We have received a communication from one of our readers dealing with the subject discussed under the above heading in our last issue. He writes as follows :—

The article under the above heading in the current issue of THE ELECTRICIAN, although somewhat belated, is the most refreshing draught the present writer has had during this season of wasp-stings and empty bottles. The invitation to your readers to co-operate with you in comparing notes as to their experiences in the field of competition should be productive of much good and useful information.

In the opening paragraph, owing to the hot weather or a side-slip of the typewriter, a wrong impression is caused by the following statement: "The *records* of the controversy show the display of a greater amount of zeal on the part of the champions of gas as compared with those of electricity." This is true only so far as the records go, as, owing to the lethargy of the electrical press, much goes unrecorded that would be most useful to those in the field. Whilst, on the other hand, our friends the enemy go to the other extreme, and record more than actually happens, as instanced in a certain gas journal a couple of weeks ago when they adduced certain *scientific* proofs from an unknown source to show that a tantalum lamp created more carbon dioxide than a gas burner in the same room under similar conditions.

With regard to their many desperate attempts to find fresh outlets for gas, the vendors of this superfluity are finding that their opportunities are becoming fewer daily, and it only requires a combined forward move on the part of all concerned in the electrical industry to co-operate as you suggest and keep in close touch through the medium of the technical press. The necessity for this vigilance is shown by the latest move on the part of the gas undertakings. Even in the past their tactics have often times been more vindictive than competitive, their real aim, wasp like, being to damage their opponent at the cost of greater damage to themselves. When their new scheme, financed by the funds being raised on the basis of 2s. 6d. per million cubic feet is launched, we must be prepared to compel them to spend it for the public good.

An allusion is also made in THE ELECTRICIAN article to the forthcoming Olympia Exhibition, and a hope is expressed that one of the outcomes of it will be a reduction in the price of metal filament lamps. This is an absolute necessity, as it must be obvious to all concerned that the inflated prices of these lamps has placed a strong weapon into the hands of our rivals, and caused the greatest set-back to many electrical undertakings which has been felt much more than gas or any other competition. The losses due to their reduced consumption have not been made up, in many cases, by additional lamps, owing to their prohibitive prices. Unfortunately, there is a difference of opinion on this question in our own camp, as recently a contemporary connected with the electrical industries, commenting on the fact that one firm of lamp manufacturers are supplying a high-voltage lamp at 2s. 6d., concludes by asking the following question: "Is the game of cutting prices worth the candle?" This lamp at the price quoted yields a clear 30 per cent. profit, without any risks whatever, and if the man behind the counter is not content with this, the only remedy is to effect a more efficient means of distribution, and the sooner the better.

This question cannot be viewed or discussed along parallel lines, as they never meet, but rather as an equilateral triangle, the base of which is the supply undertaking, the other sides being represented by the consumers and the manufacturers respectively. All other interested parties are merely adjuncts, or in some cases hangers-on. The sooner that this is realised it will be better for all concerned, and once we get our own house in order, we may hope for satisfactory results all along the line. The tail has wagged the dog too long. Much more might be added, but for various reasons must be deferred for the present, as the writer is by no means a prime mover, but a mere

LEWIS'S LIBRARY.

Messrs. H. K. Lewis have sent us a copy of their quarterly list of new books and additions to their medical and scientific library. In the scientific section we notice that the already fairly representative collection of books has been brought up to date by editions in aeronautics, civil engineering, electrical and general engineering, mechanics, mining, metallurgy and technology. In the electrical section we notice particularly the addition of the revised edition of Von Schon's "Hydro-Electric Practice," a voluminous work dealing with the practical use of water power for electrical transmission purposes. Dr. Fleming's "Lectures on the Propagation of Currents in Telephone and Telegraph Conductors" is also included and should be useful to telegraph and telephone engineers who are anxious to keep abreast of the times. Our readers should make application for particulars of the library, and also of these recent additions, to Messrs. H. K. Lewis, 136, Gower-street, London, W.C.

THE BENJAMIN FRICTION-DRIVE SCREWDRIVER.

There are innumerable instances in which it is convenient to turn a screw driver without removing the business end from the slot in the screw. The rachet screw driver is well known, but it has certain limitations and is apt to be expensive. With the Benjamin friction-drive driver there are frictional surfaces between the cap and the handle, and these engage when the ordinary natural working pressure is applied to the end of the handle. There is a spring which separates the surfaces as soon as the pressure is relieved, and the loose free end of the handle can be turned back without removing the screw. This spring maintains a slight constant pressure on the screw, holding it firmly in the slot. There is a free swivel connection between the cap and the handle by which it is possible to turn very rapidly free-running metal screws simply by the operation of the fingers and thumb. The driver can be used by either hand, and is therefore suitable for dealing with difficult places where constant lifting of the blade from the screw slot not only wastes time but is apt to be annoying. The driver is suitable for turning right or left hand screws without any adjustment. The price is extremely moderate, and two types are offered, one with diameter blade and the other with a diameter. The blade is of high-grade crucible steel carefully forged, tempered and polished, and the handle is of black insulating material moulded round the blade. The Benjamin Electric (Ltd.), 117, Victoria-street, London, S.W., will supply particulars.

BENJAMIN SCREWDRIVER.

TIME SWITCHES.

In our issue of July 28th we described a pattern of time switch which is manufactured by Messrs. Novitas (Ltd.), Zurich. We have since received a pamphlet from Messrs. Wm. Geipel & Co., St. Thomas-street, London, S.E., in which the same pattern of switch is described and priced. We are asked

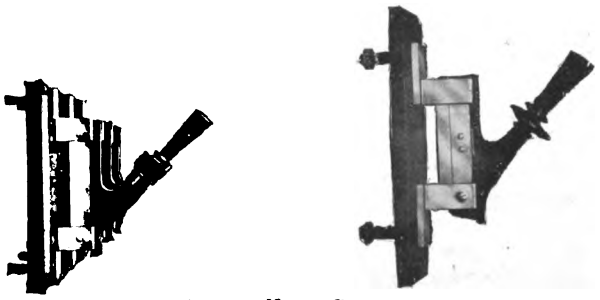
to state that this firm are placing these time switches on the market as agents for the United Kingdom and colonies. They also inform us that the switches are being used by a number of Corporations in this country, particularly by the Manchester Corporation. The switch has been marketed under the trade name of the "Arbiter."

QUICK-BREAK KNIFE SWITCHES.

The single-pole and triple-pole quick-break knife switches illustrated herewith have all current-carrying parts of hard-drawn copper. The handle is well insulated, and the risk of shock when operating is reduced to a minimum. Single-throw switches are supplied with knee-type handles only, while double-throw switches are made with straight handles only. The contacts are made in the double "U" form, and act as a guide for the blade when closing the switch. They are strengthened by mild steel stirrups which assist in maintaining pressure between the contact surfaces. The blades are made in the "U" form, and are hinged to cast-iron blade carriers. In the case of

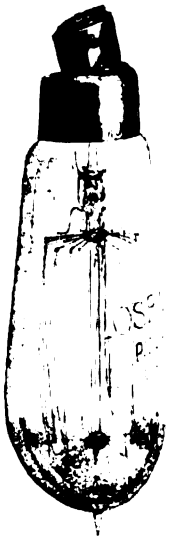


Siemens Knife Switches.

switches for currents up to 200 amperes, the whole of the blade has a quick-break action, but in larger sizes a follower blade is provided. For currents above 700 amperes, two or more blades in parallel are provided, according to the capacity. Both blades and contacts are easily renewable. In the case of double or triple-pole switches, the blades are mechanically connected by an insulating bar to which the handle is fixed. Switches can be supplied mounted or unmounted for either front or back connection. When ordering unmounted switches, the thickness of panel should be stated. The switches are made by Messrs. Siemens Bros. Dynamo Works.

WHAT ABOUT THE BULB?

The adjoining illustration has been reproduced from an untouched photograph taken of a lamp sent to the G.E.C. by Rawlings & Co., of High-street, Lee, Kent. This lamp has recently undergone and withstood a test such as does not fall to the lot of many. For some time past it has been burning in a private garage in Kent, and on Thursday the 10th it was struck by the rear part of a car backing into the garage. It is of interest to record that the only damage done to the lamp was the indentation of the cap shown in the above picture, the filament after the collision being found *absolutely intact*.



A Sturdy Osram.

THE VIBRAGRAPH.

An extremely ingenious instrument, and one which should have a wide field of application, is that known as the Vibragraph, which Messrs. Siemens Bros. & Co. are putting on the market. This instrument has been designed to give accurate records of every kind of vibration. In a pamphlet published by the makers an interesting description is given of the instrument and also several photographic records, which are termed vibragrams, of various objects, such as a house with no traffic passing and with a tramcar passing, a turbo-generator, a two-crank engine, a four-cylinder motor-car engine, &c. The instrument is of simple construction and is compact and light, therefore easily portable. In principle a small mirror is floated on mercury, a beam of light from a tiny electric lamp is thrown on to the mirror and reflected on to either a ground-glass screen or a photographic plate. In order to measure the vibrations within a wide scale three differently adjusted mercury cups are provided with each instrument. We understand that the

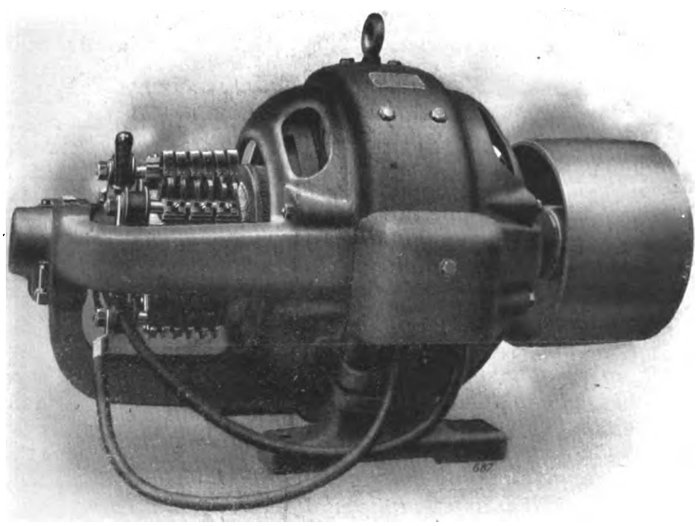
apparatus has been on test for over 18 months, and has proved highly satisfactory. It has also been used in vibration litigation cases in which municipal supply undertakings were involved.

INTERPOLE DYNAMOS AND MOTORS.

The introduction of the auxiliary pole for dynamo-electric machines at the time of the last electrical exhibition at Olympia was a matter of considerable importance to the development of industrial electric power applications. In the meantime,



UNION INTERPOLE DYNAMO.

manufacturers have carefully introduced this important adjunct into their designs, and the net results have been a cheapening in the cost of production, increase in the capacity of the machine and a reduction in its overall dimensions. Practically all dynamo and motor makers at the present time have a special line of interpole machines for direct-current working. The Union Electric Co. has just published a special list dealing with their machines of this class, and it will be found of interest to electrical contractors and industrial power engineers. We understand that in the electrical and mechanical design and construction of these machines the requirements of the British Engineering Standards Committee are complied with. The principal features of the machine are the fixed brush position for all variations of load, the fitting of a special terminal box at the side of the magnet frame, and the general provision of an extremely compact and neat machine. The machines are designed for a 25 per cent. overload for half an hour and 40 per cent. for three minutes. It is stated that the ratings are upon conservative lines, and that under continuous running conditions the temperature is always within safe limits. The machines can be supplied open, semi-enclosed and enclosed.

NEW "ARMORDUCT" CATALOGUE.

An interesting general catalogue of electricity supplies and wiring accessories is being sent out by the Armorduct Mfg. Co. The majority of the specialities of this firm have been before the industry for some years and are consequently well known. The list is the complete catalogue of the company's products and covers practically every item required by the wiring contractor. The company's conduit system and accessories is fully described in the list, and a considerable number of pages are devoted to these details. Incidentally, we may remark that the company has an extensive works at Witton, Birmingham, where all its conduit material is produced, and we give an illustration showing one of the departments of these works. We notice in the conduit section details of an interesting type of adjustable wall box which should prove very useful in difficult situations. It is not always possible to plumb up a box with the face of the wall. When the surface from which the switch knobs are to project is not in a vertical plane it is necessary to adjust the position of the bottom of the box until it becomes parallel with the flush surface. The adjoining sectional illustrations show how the Armorduct adjustable fittings box overcomes this difficulty. The switches are mounted on a back plate which is arranged with an adjusting screw in such a way that the top or bottom of the plate can be set at at any desired angle to

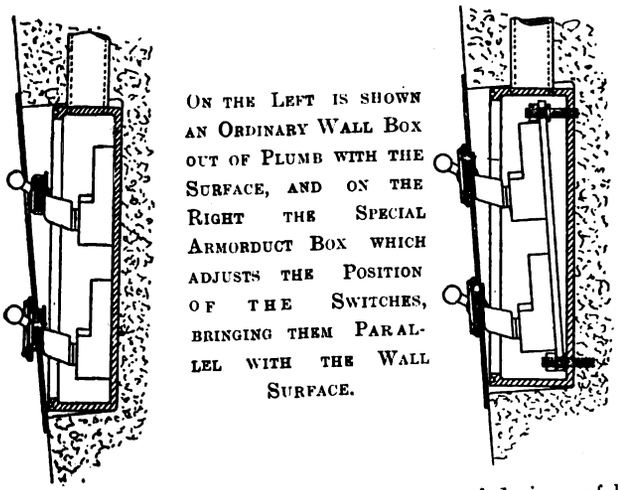
the bottom of the box. This movement enables the switch knobs to be brought into line with the flush plate covering the box on the surface of the wall.

A large amount of space in the list is also given up to water-tight fittings both for single metal lamps and for clusters.



ON THE LEFT IS SHOWN AN ORDINARY WALL BOX OUT OF PLUMB WITH THE SURFACE, AND ON THE RIGHT THE SPECIAL ARMORDUCT BOX WHICH ADJUSTS THE POSITION OF THE SWITCHES, BRINGING THEM PARALLEL WITH THE WALL SURFACE.

Details are also provided of a large variety of designs of lanterns for outside lighting. We are sure that the list will be appreciated by the trade, and would recommend interested readers to make early application for a copy.

MOTOR DRIVEN FIRE SYSTEM.

An interesting account of an up-to-date equipment for providing protection from fire is given in a recent issue of the "Electrical World." It is in use at Boyne City, Mich., which is a town of 2,000 population near the northern end of the lower peninsula of the State. The water supply of this town is derived from a well, whence it is pumped by means of an air lift, delivering into a low-level receiving basin. High-duty pumps next force the water to the reservoir on a hilltop 250 ft. above the town. The main supply to the town is through a 12 in. pipe in which, at the city limits, is inserted an electrically controlled gate, by-passed by a pressure-reducing valve. Normally the gate valve is closed, passing the town water supply through the reducing valve, and so lowering its pressure from 115 lb. to 40 lb. per square inch for domestic use. In case of fire in the town the electrically operated gate valve can be opened from the fire department office, at once impressing the entire 115 lb. pressure of the reservoir on the town mains. With this pressure no fire engine is needed to throw a good stream over any house in Boyne City.

The main lift pump is of the triplex-plunger type, and is driven by a slip-ring induction motor. The pump delivers directly into the 12 in. main pipe between the gate valve and the reservoir. When in operation this pump supplies a greater volume of water than the town demands at any time, so that the pump is continually making delivery to the reservoir. When the level of the reservoir has risen to a pre-determined height the pump is automatically shut off, being again started when the reservoir falls a given amount.

This automatic control of the pump motor is effected by a float at the upper reservoir controlling the circuits of the automatic starting panel in the pump house half way down the hill. On account of the exposed position of the float and the severe climate to which it is exposed a pilot pipe filled with oil has been provided in which the float moves. This pipe is tapped from the lowest level of the reservoir, so as to be unaffected by ice on the surface. The oil line is also so arranged that in case the reservoir is drained the oil will not be spilled. Normally this float contact controls the pilot circuit of a full automatic self-starting panel for the pump motor, but if desired the float control can be cut out by opening a double-pole switch, leaving the motor to be started from the panel by hand. The latter feature makes it possible to keep the motor off the line during hours of heavy load on the generating station. The motor driving the high-duty pump is protected by an oil switch, which also serves as a circuit-breaker. The air compressor used for blowing the well is driven by a squirrel-cage motor. The attendant in charge of the station visits it during a short time each day to inspect the operation of the equipment.

GAS AND ELECTRICAL HEAT.

We have trodden on so many of the pet corns of the "Journal of Gas Lighting" lately that it has devoted quite a considerable amount of its valuable space to the application of salve to the bruised spots. Our remarks under the head of "Can it be possible"? have caused it an immense amount of merriment, so it tells us, and it has, no doubt, got rid of much perspiration (condensed gas, if it prefers the name) in shaking its sides with laughter. We are delighted; indeed, we had grossly underestimated our esteemed contemporary's sense of humour. Maybe we doubted its existence altogether. But to return to one of the corns. We are now invited to take up the cudgels on behalf of the Berry Construction Co., about whose "Tricity" cookers, at Preston, we ventured (withou tasking the permission of the "Journal of Gas Lighting") to give a few figures. Now figures to our esteemed contemporary are like the winds about the vitals of a gas mantle, they bring on violent tremblings. Meat shrinkage in gas cookers is the cause of the trouble of the figures. The full blown wholesome appearance of a "Tricity" cooked joint is something which the gas people are incapable of understanding. They have not seen it, won't trouble to see it (why should they!), and because it does not appear "scientifically" correct, they say it is impossible and silly. Not content with a wild prancing around the hot plate of discussion, our contemporary endeavours to escape the grilling figures by abusing the author of a testimonial to the "Tricity" cooker. The insinuations are that the testimonial was influenced by the Berry Construction Co., and that Mr. Haynes, the householder in question, was not satisfied with cooking the meat but "cooked" the figures as well. Vulgar personalities were also indulged in at the expense of Mr. Haynes. These tactics are unworthy of our pugilistic contemporary, whom we have never until now had to accuse of hitting below the belt. It must not wonder that the Berry Construction Co. and Mr. Haynes maintain a dignified silence as the best "response" to such attacks. Mr. Berry is by no means "Coy." We advise the "Journal of Gas Lighting" to cultivate its old sporting style and get in, if it can, a few heavy body blows on the "Tricity" cooking proposition. It will not then be necessary for it to turn from the Berry Construction Co. to us for an explanation of the difference between gas and electrical heat.

IFS AND QUERIES.

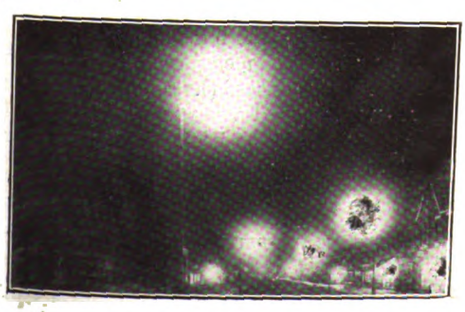
Will the other lamp makers now bring out drawn tungsten wire lamps?

Mr. Steinmetz asks a question:—What is permanent in the permanent magnet, the magnetic flux, or the magneto-motive force, or the flux density, or flux distribution, or the magnetic energy? The answers of disappointed competitors in Siemens' Tantalum poster competition will receive every consideration.

Will the Lea Recorder Co. fit their instruments to each of the bars at Olympia?

Is there any reason to suppose that, if any other lamps but Brimsdown had been used at the Carlton Hotel, the falling of debris in the recent fire would have failed to break them?

Will there be a strike of electrical contractors, and, if so, will the Electrical Engineers' Corps be quartered on their premises to maintain order and keep up the price of metal lamps?



Street illumination at Hanwell by High C.P. "OSRAMS." The lamps are fitted in "Highfield" Patent Fittings and erected on Tramway Poles.

THE ELECTRICAL CONTRACTOR IN AMERICA.

The relations between the electrical contractor and the central station engineer in this country has been discussed in the technical Press *ad nauseam*. The position of affairs as between the parties has undergone no change despite the amount of ink and paper which has been used with that object in view. If a poll were taken of the electrical contractors in the country, probably half of them would express the utmost indifference as to what the central station engineer did or did not do. The other half would be probably divided into those whose relations with the central station engineer were of the best possible description and those whose were not. The National Electrical Contractors' Association has recently held its annual meeting at Niagara Falls, and it is interesting to turn to views expressed by one of the staff of the New York Edison Co. on the subject of the contractor and the central station. We have often said that the conditions under which a supply of electrical energy is given in the United States differ vastly from those which obtain in this country. There are practically no legal restrictions of any kind, and there appears to be a delightful flexibility about the fixing of rates for various classes of consumer. Probably this is only equalled by the methods which we understand are in vogue among electrical power in bulk supply companies in this country and those municipalities who are sufficiently large to offer inducements to the power consumer. "The Electrical Review and Western Electrician," commenting upon Mr. Williams' Paper, to which we have referred, throws some interesting sidelights on the position of affairs "on the other side." It says: "Very often it is necessary in the carrying out of a campaign, looking to the introduction of current-consuming devices as a necessary adjunct to building up the central station load, that the company must strike a bargain with the customer and prospective consumer." This indicates that the consumer is offered special inducements in the matter of price, to come on the mains. Probably he has a private plant, and only a specially low rate will tempt him to scrap this and depend upon the public service. Over here we have very few opportunities of striking bargains of this kind. Then again our contemporary says: "Where a campaign having for its purpose the introduction of heating devices, electric fans, portable lighting outfits, domestic appliances such as washers or vacuum cleaners, is projected, the contractor stands no chance whatever in the matter of meeting the central station company's price for the apparatus. However, there should be no animus upon the part of the contractor in an incident such as this. While it may deprive him of a small profit which he might make as a merchant, so long as the central station company is not entrusted with the wiring of the premises or the installation of the apparatus, every device that is sold improves the business of the electrical contractor."

This matter of the price of the central station for electrical apparatus being below that of the contractor is one which we have had little occasion to deal with on this side. We understand there have been complaints against some show-rooms in London and the provinces for offering apparatus at list price. Where the station man has been inclined to embark upon a price-cutting campaign the contractor has been able to check him. But the real point of our contemporaries' remark in this connection is that relating to the wiring of the premises and the installation of the apparatus. It seems as if here the American contractor has been able to take a firm stand, and obtained a recognition of his real position in the contracting business. While we do not say that the station man should be able to sell apparatus, at the same time it would be something of a solution of the difficulty between the two parties if the contractor were satisfied to carry out the wiring of the premises and the installation of apparatus, leaving the central station authority to run its own showroom and bring the merits of electricity consuming devices particularly to the notice of the public.

Mr. Williams lays some emphasis upon the position of the big contractor in the United States and the power which he possesses in persuading the user of private plant to abandon this installation and take a supply from the mains. Evidently this class of contractor has firmly established himself in such a position that he can make an important deal on behalf of his client in the matter of obtaining exceptionally low rates for the public service. Another significant remark of Mr. Williams is that, first and foremost, the contractor is entitled to a square deal. He says: "For business reasons, as well as for absolute justice, fair and generous treatment should be accorded. If this is done, in 99 cases out of 100 the contractor will pass on to his customers the impression that they, too, may expect a square deal from the station and the proper adjustment of whatever differences may arise between the company who sends the bills and the consumer who pays them." Here again we get a further interesting sidelight on American practice. Evidently the average consumer is enticed on to the mains by a system of bargaining, and if the contractor gets a square deal from the station he persuades the consumer that he also is likely to get the same. We have advanced a stage beyond this point in the relations between our central stations and their consumers, and we think the cases are few and far between where the station engineer has to cavil with the consumer over the bill. We can imagine the feelings of British central station engineers if we suggested that it would be necessary to placate the contractor and fix up with him what the Americans call a square deal before he (the central station engineer) could be certain of working upon amicable lines with the consumer.

A.E.G. PROGRESS.

We have received copies of the July and August A.E.G. "Journal," and must compliment the company upon the excellent arrangement and high quality of the matter therein. In the July issue there is an interesting article on the new steam turbine shops at Berlin, the lay-out of which is strictly in accordance with modern practice. On the cover of the issue is an illustration of a 12,000 kw. turbo-alternator, which is shown on the test plate at the works, side by side with a turbine-driven boiler feed pump for the same set. It is stated that the new shops are specially suited for the construction of large capacity turbines up to 20,000 kw. units. Interesting details are also given of turbine-driven centrifugal pumps. We may particularly mention one vertical pattern, in which the turbine is direct connected to an air pump and water-extracting pump, the design being specially for marine purposes. Two interesting railway systems are described in the issue, that at Bitterfeld, which is a 10,000-volt one-phase trolley line, and that at Hamburg, which is a direct-current operated elevated line. Of interest to manufacturers, particularly at the approach of the Olympia Exhibition, is the description of the A.E.G. exhibit at Munich, where a special electrical exhibition for domestic appliances and small industries and agriculture was opened under the auspices of the Elektrotechnische Verein.

In the August number the steam turbine article is continued, and an interesting comparison is made between the reciprocating pumps at the Hamburg waterworks and turbo-driven pumps. It is shown that three of the former, of 300 H.P. capacity each, occupy a greater amount of space than two of the latter, one of 900 H.P. and the other of 300 H.P. Views are also shown of the turbo-compressor shop, this being a comparatively new application for steam turbines. The description of the Bitterfeld line is continued, with an account of the locomotives used for the haulage of the passenger trains on this line. Each locomotive is fitted with a 1,000 H.P. alternating-current commutator motor, which is coupled to the two driving axles by a connecting rod at each side of the locomotive. These connecting rods are placed in a vertical plane. The maximum speed of the driving wheels is 400 revs. per min. This type of locomotive has been in use on regular passenger service since the beginning of the year. The August edition is concluded with an interesting account of the A.E.G. plant at the Cedegolo station of the Adamello 72,000-volt power transmission scheme. The equipment includes five 5,000 H.P. Pelton water wheels direct connected to A.E.G. generators, which generate three-phase 42-cycle energy at 9,000 to 12,000 volts. This voltage was decided upon to enable the plant to run in parallel with that at Isola, which is part of the same power scheme, but is some 4 miles distant. The switchgear is also A.E.G. design, and considerable ingenuity has been shown in the lay-out of the 72,000-volt equipment.

TRANSPORTING TRANSFORMERS.

The growth of hydro-electric plants on the Continent and America has given rise to the necessity for transporting completely assembled transformers by rail. Most of these pieces of apparatus reach up to a considerable height, and as they must be shipped in a vertical position it is necessary to place them on some special form of car which will admit of the transformer being kept in an upright position, and also of its passing successfully through tunnels and under bridges. A special type of car has recently been constructed for the American Westinghouse Co., which has a capacity of 75 tons in the well of the car. The type of car adopted is one with bogies at each end and a dropped centre forming a well in which the transformer is placed. The car frame is of heavy steel girder construction, and the bogies are fitted with 36 in. wheels of rolled steel. The total capacity of the car for a weight distributed evenly is

205,000 lb. The car is fitted with Westinghouse brakes and Westinghouse friction draught gear. A description of the car published in our American contemporaries includes an illustration of a 2,000 kw. 60-cycle 101,200 volts transformer of the oil insulated tubular self-cooling type, built by the Westinghouse Co. for the Southern Power Co. The top of the transformer when in position on the car was 16 ft. above the level of the rails, the surface of the floor of the well about 2 ft. 2 in. above the tops of the rails.

This is an interesting development and serves to show the extent of the business done in America in hydro-electric plant and apparatus. The particular type of car solves the problem of railway transport, but it would be interesting to know how so large a piece of apparatus is conveyed up country to the actual site of the station. Very often only mule tracks are available, and it is sometimes necessary to lower plant and machinery several hundred feet down the face of a cliff.

TEN YEARS OF THE "JANUS" INTERCOMMUNICATION TELEPHONE.

The "Janus" system of intercommunication telephone for large private offices was invented some 10 years ago by Messrs. Mix & Genest, of Berlin. It differs somewhat from the ordinary intercommunication system, in that in one office instrument may be combined connections both to the other offices in the same building and to the city and trunk systems. Further, a special arrangement enables one person who is speaking to another on the city system to discontinue his conversation for a minute or so without being cut off, and meanwhile to make inquiries from another office in the same building. That is to say, should a client ask for certain information which the person rang up is not able to give, the latter could get into communication with another man in the same office and carry on a perfectly private conversation on his instrument without the outside connection being severed.

The "Janus" telephone is made in the two ordinary types, namely, the wall and table instruments. A number of switches are provided in accordance with the number of instruments on the circuit, and besides there is a black knob which, when pressed, enables the instrument to be directly connected with the central exchange. When this is done a signal in the instrument indicates whether the wire to the exchange is free or not. In the same way, by pressing either of the white knobs a connection can be made to any of the offices in the same building. If one of these white knobs is pressed while a conversation is going on with a subscriber on the main exchange the black knob springs automatically back to its off position, thus cutting the instrument off the subscriber and ensuring privacy of conversation.

In celebration of the successful working of this system of instrument over 10 years, Messrs. Mix & Genest have issued a pamphlet, a copy of which has been sent us. After describing the essential points of the instruments and illustrating the various types made by them, a series of interesting photographs are to be found showing examples of large offices, Government buildings, mines, foundries, swimming baths and other similar places where this system of intercommunication is used. These buildings include the Ministry of Trade and Industry at Berlin, the Palace of Justice in the same city, the Rheinish-Westphalia Bank at Dusseldorf, the new swimming baths at Breslau, and several mines in the coal district. In many of these large offices, of course, a sub-exchange is used. In this case the operation of the system is exactly the same, except that when the black knob is pressed communication is made to the sub-exchange instead of direct to the main exchange. The number is then asked for in the usual way. This does not interfere with the direct intercommunication system between the various rooms in the same office described above.

Messrs. Mix & Genest have also arranged a control set, which can, if necessary, be installed in the manager's office. This instrument consists of the ordinary hand combination mounted on a small desk. On this desk is mounted an ordinary telephone glow lamp and a special control switch. Directly a call to the main exchange occurs the glow lamp lights up. The chief, by pressing the control knob, can then listen in and find out whether the conversation is being conducted for purely business purposes or not.

THE MERITS OF CO-OPERATION.

Among the various electrical interests in this country there is probably the minimum amount of co-operation. By this we mean the desire to meet and discuss questions which affect the industry as a whole. We have the Institution and various Associations, each of which has been formed with the idea of obtaining the advantages which only concerted effort can procure in any business. Up to the present the history of these combinations does not furnish enough evidence to show that their existence is altogether justified. Co-operation would, of course, be particularly welcome among the manufacturers. This section of the industry may be regarded as the basis from which all else springs, and it should present a degree of solidity to act as a firm foundation for the rest of the structure. We are apt to compare the position of the electrical industry in this country with that which obtains on the Continent and in America. The comparison is in no way just or reasonable. Our geographical position and configuration and our markets and conditions of labour necessitate that our case should be considered entirely on its own merits.

We cannot look to the Institution of Electrical Engineers for measures which will place the manufacturing element upon an organised footing. We do not refer to the individual management of the various manufacturing concerns. That is a matter which must always remain independent of outside influences.

J.C.P.

There is enough evidence to show that all the recognised manufacturing firms in this country conduct their establishments upon modern lines; in fact, this must be so, otherwise they would not be in the position in which they are to-day.

Turning to the various associations which have been formed to concentrate attention upon the requirements of individuals or firms there is a lack of cohesion and an absence of directive effort which can only strike the observer as remarkable. Valuable years have been allowed to elapse, and the associations have done little more than pull themselves together as such. There have been no attempts at co-operation between the parties, because the objects of the respective associations have been considered to be in every way divergent. This is all the more deplorable because if we have anything to learn from Continental and American experience it is in the direction of concentrated effort on the part of manufacture and the interests, industrial, commercial and domestic, which spring from it. Concentration has built up the United States and Germany.

While we keep in mind, as we have already said, the peculiarity of the conditions which govern industry in this country, we feel that the actual example of concentration and concerted effort should be followed in our own case. There are innumerable ways in which concerted action of the electrical manufacturers in this country should result in expansion of every branch of the industry. The railways are not yet electrified, and will continue under steam conditions until a sufficient weight of evidence, which can only come by co-operation, has been brought to bear upon the railway companies. The suburban traffic problems of most of our large cities can be solved by electric traction, and here again the disjointed efforts of a few manufacturers are inadequate to bear down the prejudice which it is necessary to remove before definite steps can be taken. There is the gigantic gas industry in the country which needs to be vigorously fought for some years until it has been forced to take up its legitimate position as a supplier of gas for heating purposes. There are vast fields of industry in which electric power is as yet unknown. There are openings for uses of electrical energy in agriculture. Most of these matters require action on the part of a representative body which can assist toward the desired end by legislation and by the publication of literature which will further the efforts of manufacturers themselves.

It seems extraordinary in an industry in which the concentration of power plant is advocated and practiced, that there should be so little concentration and effort among the interests which go to make up this industry. A score of years ago a dozen manufacturers built a dozen different small dynamos. To-day the dozen dynamos are rolled into one, but the number of manufacturers has not decreased. Surely the coming generation of electrical engineers will see to it that there is some change made in this state of affairs. Mr. Ferranti has pointed the way. Is it not time that we set out on the road?

A BUYER'S CATECHISM.

Some months ago we published a salesman's creed, and we have now been supplied with a copy of a buyer's catechism. This is being issued by the Silent Electric Clock Co., who are anxious to catechise would-be purchasers on the lines of the publication referred to. Each of the questions is answered in the printed catechism, and we understand that if our readers would care to ply the company with further questions they will receive satisfactory answers through the post. The catechism is a novel form of advertisement, and a copy will be forwarded on request. The company's address is 192, Goswell-road, London, E.C.

THE RUPING PROCESS OF CREOSOTING.

The creosoting of telegraph and electric light and power transmission poles has been practised with fair success for a considerable number of years. It has been found, however, that the weakest point in any creosoted pole is that immediately above the ground level. It is at this point that the moisture, air and warmth which are necessary to the formation of fungus are to be found. The result is that after a certain period the pole shows signs of eating away. Hitherto it has been impossible to prevent this attack upon the pole at this weakest point, as the ordinary process of creosoting does not afford immunity from trouble. We are informed by Messrs. Richard Wade, Sons & Co., Ltd., Hull, that the greater part of the troubles with poles is due to the above-mentioned cause and that they have taken steps to introduce into their business the Ruping process of creosoting by which the actual walls of the cells which go to make up the timber are saturated with the preserving fluid. The aim of the inventors of this system has been to protect the substance of the timber without wasting the preservative. In the ordinary red fir-tree, which is mostly used in this country for poles, there is about 40 per cent. of what is known as heart wood, which cannot be impregnated to any appreciable extent because the cells become closed. The balance of the tree is made up of sap wood, which is open cellular tissue. This is comprised of the substance or fibre of the tree and a number of open spaces, in the proportions of about half each. It is the fibrous portion of this part of the tree that is specially treated by the Ruping process, which at the same time leaves no preservative in the interior of the cells. We understand that a considerable amount of research work has been carried on in connection with this process, and these investigations have shown the fallacy of supposing the decay of the wood has been caused by something in the tree itself. The wood is actually attacked from the outside, and not from the inside. We understand that in the Ruping process no new substances such as antiseptics or germicides are introduced. It really constitutes a new method of introducing ordinary creosote into the wood. It was at one time supposed that the creosoting of timber by the ordinary method prevented the absorption of moisture by the wood, and that for this reason it was impossible for decay to take place. Messrs. Wade point out that a number of tests were made a few years ago by certain English railway companies which satisfactorily disposed of this fallacy. A number of telegraph poles were weighed wet out of water and again when dry, and a third time after creosoting. Subsequently they were weighed at intervals, and it was found that the creosote did not prevent the entrance of moisture. There is also a tendency for the creosote to drain out of the poles when they are placed in a vertical position. Experiments have been made which show that the loss of creosote will amount to from 7¼ to 9½ lb per cubic foot over comparatively short periods. The Ruping process has been introduced to prevent this. It is claimed for it that there is a thorough saturation of all parts of the timber which can be saturated by the preservative, that there is an absorption of only so much liquid as is necessary to accomplish this, that oozing and sweating of the wood is completely prevented, the timber being dry and clean, and that there is a great saving in cost without reducing the life of the timber. The process has been extensively employed on the Continent and in America, where upwards of the equivalent of 38,900,000 sleepers 9 ft. by 10 in. by 5 in. have been put down. Messrs. Wade have taken up the process on behalf of Great Britain and the English speaking Colonies, and we understand that they will be shortly making a demonstration at their works of the process. The company is to be complimented upon its enterprise in taking up this process, because it will enable it to get rid of one of the most serious troubles with telegraph, telephone, and transmission line poles.

ALUMINIUM TROLLEY HEADS.

The use of aluminium on the Continent for bow collectors on tramways is now quite general. The trolley wheel is the exception rather than the rule. The durability of aluminium has been practically demonstrated on the modern bow collector, and the satisfactory results obtained point to the special utility of this material for this purpose. In this country we have pinned our faith to the trolley wheel, and although the bow collector would be very much quieter there seems to be no possibility of changing over to it. Aluminium may, however, be used in the trolley head. It has been found exceptionally valuable as a support for the trolley wheel at the business end of the trolley pole. It is extremely light and at the same time is sufficiently tough to stand up to the hard wear which is imposed upon a fitment of this character. We illustrate a pattern of trolley head made by the British Aluminium Co. and supplied to a large number of tramways. This particular pattern has been in service over a period of nearly two years, and during this time had run 50,080 miles. The car was actually in service 626 days. The weight of this particular pattern of trolley head without the wheel is 2 lb. 2 oz. The trolley tension is 16 lb. We understand that this trolley head gave no trouble at any time. The use of a lighter metal for trolley-heads together with a lower spring pressure will naturally have a beneficial effect upon the overhead work. The metal used is one of the standard light alloys of the British Aluminium Co., having a specific gravity of only 3·10. There is thus a saving of about 60 per cent. on the weight of gunmetal or phosphor-bronze. When the hammer-like action of the trolley on the wire is considered, together with the accompanying heavy maintenance expenses, a reduction of from 3 lb. to 4 lb. in the weight of the trolley-head will appear as a potent advantage. The low-tension on the trolley boom may be relaxed in proportion, whilst maintaining good contact between the trolley wheel and the wire. The trolley head illustrated was made by Messrs. Brecknell, Munro & Rogers.

MERCURY VAPOUR LAMPS.

The lighting season is upon us and the lamp makers are getting busy with their trade literature. The Westinghouse Cooper-Hewitt Co. is issuing a number of lists which describe the Westinghouse silica lamp for d.c. and a.c. circuits and illustrate a number of interesting installations which have been carried out. The mercury vapour lamps for a.c. circuits are arranged to burn in series in circuit with a mercury vapour converter. This is a simple piece of apparatus and requires no attention. It is self-contained with the switchgear for the turning on and off of the lamps. The lamps are supplied for one-phase circuits 40 to 60 periods. The voltage on the d.c. side is 35. The converter is included in the price of the lamp. The energy consumption is stated to be 0·33 watts per candle, or a total consumption, including that of the converter, of 175 watts per lamp. These figures show a greater economy than arc lamps or metal lamp clusters. A fitting known as the Saturn type is also described in which there is a large central globe containing the lamp, and metal lamps which are hung at equal distant points round the equator. These lamps supply the necessary red rays which are, of course, eliminated from the light of the silica lamp. These lamps light up as soon as the switch is turned on, and the silica lamp is tilted by hand for lighting purposes. We published a description of this silica lamp in our issue for September 23, 1910.

The company are also offering what they term a light transforming reflector for use with their lamps. The principle of this is based on the phenomenon of fluorescence, a portion of the primary illumination being actually transformed and the reflector acting as an auxiliary luminous source. We understand there is no appreciable loss in luminous intensity. It is stated that with this reflector an agreeable white light is produced, having a slight rosy tint.

AMERICAN ADVERTISING METHODS.

"Two hundred and fifty thousand bulletins in six days, siree! That's what I call publicity, and, geewhizz, arn't we just busy in our department!" And with all our persuasive eloquence we could not convince our "hot air" Yankee that it's none of it any good for the British market. There must have been tens of thousands of pounds spent in this country on attempts to sell every conceivable kind of article by American advertising. It's a pity that those who have wrecked their own publicity ship on this attractive but rocky coast have done nothing to erect a lighthouse, warning others of the danger. But if a firm has quietly lowered 50 or 60 "thou" over the side it does not want to sing about it. The "other" man may do the same for all it cares; he's a rival and his money "don't count."

In the electrical industry up till quite recently most of the money allocated to advertising has been devoted to technical and trade papers. There has not been any need to appeal directly to the public through posters and the lay newspapers. The "popular electricity" idea, however, is changing the policy of many electrical supply houses who have planned or are already planning campaigns for circularising and newspaper advertising for such things as metal lamps, vacuum cleaners, electric irons, kettles, &c. These electricity consuming devices are deserving of attention at the hands of the public, and are likely to interest them in a mild kind of way, at any rate at present. A note of warning may, therefore, we think be sounded at this juncture to those manufacturers who have a leaning towards American advertising methods.

In the first place it must be remembered that the householder and tradesman are already pestered with literature which is delivered either through the post or by hand. They are used to it, and recognise it as soon as they see it. "Another of those confounded ——— lamp things. Oh, give it to Willie to play with." Even this treatment may be regarded as exceptional, the more usual fate for the appealing document being the W.P.B., unopened. So far as we can see there is no need for the electrical manufacturer to ply the consumer direct in this way with arguments in favour of his line. If he persists in adopting this policy he is overlooking those more efficient distributing agencies—the Publicity Committee, the electrical contractor, the ironmonger and the central station engineer. They will handle his stuff more readily, too, provided that the style of the literature is not of the American "tub-thumping" order.

We are not inveighing against circulars, bulletins, leaflets, &c., as such. They are most useful reminders when sent with accounts or wrapped in parcels or handed out at Exhibitions. But they are unwelcome to the average Britisher when shot at him from the short range of his breakfast table. The electrical supply house must have this in mind unless it is anxious to throw its good money after bad.

Much the same may be said of electrical poster advertising and display announcements. That strong sense of exaggeration which is so dear to the American heart must be rigorously excluded from the policy of the publicity manager who is voicing an appeal for electrical goods. Let it be remembered that we Britishers have made our advertising what it is—dignified, artistic, attractive. That is the verdict of globe trotters who have had opportunities of comparison. There may be a little to learn from American advertising, but we think it requires the most careful application to electrical publicity. Home methods are best.

CONNOLLY'S ENAMEL INSULATION.

For many years attempts were made to coat a bare wire with a thin covering of enamel which would have a high insulation resistance, be capable of resisting chemical action and mechanical damage, and show no signs of deterioration under the action of moisture. Some years ago Messrs. Connolly Bros. introduced an enamelled wire which they offered to the electrical trade for bell wire circuits, for winding solenoids for instruments, circuit breakers, small field coils, &c. The company has obtained an exceptional degree of success with this insulation, and they have now issued an interesting booklet which is one of the best publications on the subject of enamelled wire that we have yet seen. The entire situation from the initial experiments to the present position of the development of the material is reviewed in detail. We would strongly recommend electrical contractors and electrical manufacturers to make a study of this interesting publication.

On the ground of chemical tests the enamel-coated wire has been tested with a number of solvents without showing any signs of their influence. Among these solvents we may mention a 4 per cent. caustic soda solution in which the wire was boiled for several hours, a 10 hours' immersion in a 10 per cent. ammonia solution, 2 hours' boiling in a saturated salt solution, an hour's immersion in equal parts of alcohol and acetone, a 20 hours' immersion in a warm saturated solution of bisulphate of soda, and 5 hours' cold immersed in a solution made up of equal parts of absolute alcohol and 30 per cent. solution of caustic potash. These are some of the most interesting tests described in the booklet. The insulation resistance of the material has been severely tried from time to time. A single layer of No. 20 wire was wound on an iron spindle 1½ in. diameter and 1½ in. long, and test pressures were applied varying from 150 volts to 2,000 volts alternating current on the three grades of insulation manufactured.

Numerous tests were also made to ascertain the flexibility of the enamel. The enamel-covered wires are quite suitable for winding coils of the smallest diameter without fear of removing or cracking the enamel. It has been found that the enamel breaks with great reluctance and not in the way that a brittle or metal substance breaks. It is recommended that the enamelled wire should not be bent round a cylinder less than four times its own diameter. Amongst the uses to which the makers recommend that the wires should be put we may mention arc lamp coils, electric bell indicators, telephone receivers, induction coils, solenoid switches, air-cooled transformer windings, dynamo and motor field coils, armature coils, telephone central station connections, electric bell and telephone line wires. With the experience gained since the introduction of the wire the manufacturers state that they now have no hesitation in recommending their class C type of enamel insulation for electric light circuits up to 220 volts. This is an interesting development and one which central station engineers and contractors should take special note of. We understand that the Bradford Corporation has approved of the use of this class of wire for drawing into conduits. Messrs. Connolly Bros. inform us that they will be pleased to forward copies of this interesting list, together with samples of enamelled wire, to interested inquirers.

G.C. RAILWAY ELECTRIC SIGN.

With its customary enterprise in giving publicity to its service the Great Central Railway have just erected an electric sign of rather novel construction and design. It runs the

ASTON, BIRMINGHAM.

entire length of a 50 ft. wall, directing the traffic coming both ways along the Marylebone-road down to the Great Central station. The wall has been built up to suit the sign. The sign itself is of the standard construction which Messrs. O. C. Hawkes have adopted in all their railway work. It is built up of massive channel iron frames with T-iron divisions and sheet-steel sides. The main features of the sign are the colouring and its size; we believe it to be the longest sign of its kind in this kingdom.

THE G.C.R. SIGN BY NIGHT AND DAY.

In the design and manufacture of this class of glass faced sign it is a difficult thing to achieve novelty. In this case the size of the sign has rendered it possible for the manufacturers to create a novel effect by mounting each letter alternately on a different ground colour. We do not know whether the prevailing aim for Coronation effects has had any influence in the matter, but the letters are white, while the groundwork is alternately red and blue. The letter is of ornate design, being lined with gold and shaded black, which gives a distinctive appearance to the sign by day as well as by night.

In construction the heavy angle-iron frames, dovetailed and brazed at the corners, and the T and channel-iron divisions and bracing pieces are made in such a fashion that, given proper painting at due intervals, the sign is practically everlasting. The glass work is also limited to natural colours, and the work on them is permanently engraved, so, beyond the accident of breakage, they cannot be injured in any way. The internal wiring, as in all Hawkes standard signs, is done with 2,300-megohm Association cable, and porcelain non-corrodible holders are used, features which should reduce the maintenance charges to a minimum.

The Great Central Railway in their adoption of alternate colouring of the letters of their signs have in view what we think should be the aim of every sign buyer—a distinctive appearance for the sign—an appearance which immediately suggests to the observer the Great Central Railway before the wording is actually read.

We are indebted to the Publicity Department of the Great Central Railway Co. for photographs of the sign, and to Messrs. O. C. Hawkes for general details of its construction.

"GRAPHIC" INSTRUMENTS.

Confusion often arises between a "watt hour meter" and a "recording wattmeter" (owing to the latter expression being loosely applied to both instruments). Everett, Edgcumbe & Co. have accordingly decided as far as possible to abandon the term "recording," and to speak of a "graphic" ammeter, wattmeter, &c. By this means it is felt that all possible confusion will be obviated, and it is hoped that this example will be followed by those responsible for the drafting of specifications and the placing of orders.

The new instruments which this firm are making include voltmeters and ammeters for continuous and alternating currents, wattmeters for continuous single-phase and polyphase circuits whether balanced or unbalanced, speed and frequency indicators, pyrometers, pressure and vacuum gauges, and, in fact, for any and every purpose for which a graphic record may be required.

Fig. 1 shows the general appearance of a graphic voltmeter. The exceptionally large glass window will be noticed through which a long length of record can be clearly seen, and also the special spring fastening which affords a dust-tight joint and yet can be opened with one hand. A padlock, or seal, can be employed, if thought desirable. Fig. 2 shows the internal appearance of a moving coil graphic ammeter. Covering the permanent magnet, and shielding it from stray magnetic fields, is a detachable hood, which is seen as a shadow in the figure. A roll of chart is inserted between spring centres above the clock and passes down under two springs and a toothed guide wheel in the centre. Under this latter lies the driving wheel of the clock mechanism. The arrangement is such that the

chart cannot possibly slip, and the guiding is so accurate that all tendency to creep to one side or the other is avoided.

Below the clock is a roller on which the chart can be made to wind itself up, if required. On the right hand side is the winding lever which, owing to the construction of the case, is quite accessible. Below this lever are the change wheels whereby any desired paper speed can be provided. Any subsequent change in the chart speed can be carried out in a few moments, and without returning the recorder to the factory. Further, by means of a simple gear-changing device, two or more speeds can be provided on a single instrument, so that the same recorder can be used for widely different purposes. For example, a speed of 1 inch per hour can be provided for ordinary work, and this can instantly be altered to, say, 1 inch per minute for use in connection with machine tool driving.

A special feature is made of a hinged pen arm which can be at once removed for cleaning or replacement. The simplicity of the operation is well shown in Fig. 3, which indicates the method of removing it by merely pressing together the two arms of the spring fork between the finger and thumb. Amongst the advantages claimed for this construction of pen are, besides ease of removal, a constant and readily adjustable pressure on the paper, and the maintenance of a high insulation resistance between the current-carrying parts and the pen, which last is a most important point, particularly in connection with traction and other earthed systems. The chart over which the pen moves is perfectly flat. The pen itself takes different forms according to the purpose for which it is to be used—that is, according to whether the paper speed is high or low and the load a steady or variable one, and so forth. Again, the damping, which is provided by means of an oil bath, is adjustable so that any required degree of dead-beatness can be obtained. Special care has been devoted to the construction of the clock, so as to provide ample driving forces and to enable it to withstand the rough treatment so often meted out to a "graphic" instrument.

RIVAL LAMP MAKERS AT CRICKET.

We understand that for the third year in succession the Tantalum Cricket Club has met the eleven of the Imperial Lamp Works, and has come off with a third signal victory. The "Brimsdownites" batted first and knocked up 30 runs. This effort was responded to by 128 scored by the "Tantalites," who even then had five wickets in hand. It is pleasant to record these friendly rivalries between concerns which meet in the sterner fields of commerce. The secretaries of both clubs wish us to specially note that the meeting of the rivals is intended to be in no way a test of the merits of their respective works products. Doubtless the "Tantalites" wore the "Satisfied Consumer" expression during the match, and the "Brimsdownites" were given an opportunity of "Seeing things in a better light."

AN INDUCTION MOTOR CONTROLLER.

The type of reversing controller for induction motors mostly used in colliery and similar work is that in which a revolving contact drum is employed. A new type of contactor controller has been designed to obviate contacts rubbing on a slowly moving drum for the make and break, and in order to ensure that the maintenance shall be extremely low under all conditions of service. The maintenance cost of the drum controller has been found to be considerable. Small replacements, however trivial in cost, always cause inconvenience and expense. A controller which will avoid any excessive wear on contacts and give a positive action should appeal to power users. The contactor system, which gives quick break and make and maintains the surfaces smooth and clean with a minimum of surface wear, has been adopted in the new controller to which we are about to refer.

The method of making contact will be seen from the diagram, which shows that there is a fixed frame on which is carried the spindles A1, which extend almost the entire height of the controller. Pivoted on each of these spindles are movable arms, A2, to which are fixed contacts, A3, each spindle carrying the number of arms with contacts corresponding with the steps of the rotor resistance, of which there are usually nine, with one-step full resistance. These arms, A2, have a rotating movement on the spindle and also a small lateral movement, the combination of these movements ensuring that the contact pieces shall approach one another (when making circuit) at such an angle as to ensure a good wiping contact. Corresponding with and registering horizontally to these contacts, A3, are the same number of fixed contact pieces, B1, mounted on vertical standards, B, but insulated therefrom by mica. Each of the movable contact pieces A3 is held extended to the left by means of a spring, the spring movement being limited by blocks, A5. This addition ensures that in each case when contact is made between the two contact pieces A3 and B1, any wear or unevenness of alignment will not cause sparking as in the closed position, and perfect contact is made against the full compression of this spring. A main operating pillar, C, is actuated by the controller handle and carries a number of cams, each cam engaging with one of the movable cradles A4, on which are pivoted the movable contact arms A2.

The first operation of the handle moves a cam which closes the stator circuits. At this point the motor is connected

to the line and with all resistance in. The next and following notches actuate the movable contacts in turn, moving them forward through the necessary path to make contact with the fixed contact pieces. An automatic device is fitted to the handle which prevents the operator from moving forward more than one notch at a time. The time allowed between the notches permits the motor to accelerate the requisite amount before it is possible to pass to the next notch. To stop the motor the controller handle can be brought rapidly to the "off" position, the whole of the speeding-up action being reversed, and the stator connection broken last.

For starting up the motor in the opposite direction a handle is brought into operation, the movement of which raises or lowers the reversing drum so that the stator connections are reversed. The reversing handle is locked in position by the first movement of the controller handle. Also the controller handle is locked by the reversing handle in any intermediate position of the latter. Most users of controllers for large induction motors have found that the removal of the contact drum for examination has been exceedingly troublesome. The contacts usually have to be lifted for examination by means of a derrick or other means, and when so raised are at a very inconvenient height for effecting repairs. In this new type of controller the casing of the controller moves vertically up and down in guides, giving complete access to the contacts.

The weight of this casing, including the oil, is taken by a counterweight. All current-carrying parts are immersed in oil, and the lowering of the controller case which contains the oil leaves all the contacts exposed and at a convenient height for inspection or repair. These controllers are usually supplied with 10 positions in either direction, and although this number is rather less than is usually considered necessary in a drum type of controller, a much smoother acceleration is obtained than is possible with the older type.

These controllers can be supplied in two forms, A and B, respectively, for three and two-phase wound rotors. Both can be used for either balanced or unbalanced regulation.

The controller is small compared with the older forms in use. It is of the vertical type and the average dimensions are 5 ft. high by 2 ft. 7 in. wide. The operating handle is at the top as in the tramway type of controller, and the reversing handle is on the right-hand side.

All current-carrying parts are mounted in the tank and are oil immersed. All insulation is mica, no other composite substances or wood being used. In addition, all similar parts of the controller are interchangeable. These controllers are said to be easier to operate than the ordinary drum type. It often happens that the operator is signalled to stop instantly, and then—the next moment—he has to reverse and re-start. This may occur several times at short intervals, as in the case of a derailment at some joint in a haulage-way. Ease of operation as well as a definite indication of the direction of travel are, under such circumstances, very important features. The controller has a wide number of applications for industrial power purposes, and its introduction should be followed closely by electric power engineers and contractors.

This interesting controller is made by Messrs. Dick, Kerr & Co. of Preston and London, and they will be pleased to forward additional particulars on request.

THE ELECTRICIAN COMMERCIAL AND INDUSTRIAL SUPPLEMENT.

C. & I. Supplement No. 101.] SEPTEMBER 8, 1911. [Gratis to Subscribers.

ELECTRICAL PUBLICITY AND THE ARTIST.

Ever since Messrs. Pears succeeded in obtaining an advertisement picture from one of the world's greatest painters, the manufacturer who has any public appeal to make has endeavoured to go one better than "Bubbles." From this celebrated beginning—and an effort which has never been surpassed—there arose the idea of commissions to well-known artists to execute designs which should voice the manufacturers' appeal to the public in the most attractive and least offensive form. The "Bubbles" stage in the progress of the artist into advertising was passed through some years ago and the "funny" or "Hassal" stage entered upon. Hassal, who is a sufficiently eminent artist to make a name outside advertising, ushered in the idea of the humorous poster and for some years contributed quite the best of the displays made on the public hoardings. The net result of these two developments in advertising has been the creation of a fashion or craze among manufacturers and publicity men for some *chef d'œuvre* of a well-known brushman for use as a piece of advertising matter. This craze has found its way into the electrical world, and we are bound to say with but indifferent results.

The failure of the famous artist to make good in electrical advertising may be attributed to two causes. Probably the first is the difficulty of obtaining an enormous fee for a really good piece of work, and the second may be the failure of the artist to produce a satisfactory result owing to the essential peculiarities of electrical devices and their presentation to the public in the right way.

All things considered, the experience of the electrical industry with the "famous artist" has not been a happy one. Publicity men have paid good sums for submitted designs and pictures, but almost without exception these have not been suitable for public distribution.

This disappointing result suggests the conclusion that there is no field in electrical advertising for the work of the good painter whose name has been made outside the realm of publicity work. It is wrong to suppose that because a design bears the signature of a well-known artist, the manufacturer or publicity organisation will secure any greater prominence for the line they may be pushing in the sketch. It is the *tout ensemble* of the picture which must first impress the public, not the peculiarly fashioned signature or initials of the artist in the corner.

Furthermore, the electrical manufacturer in seeking the services of the outside artist to do his work is overlooking the many good men who have built up businesses within the confines of the industry. These men are quite capable of doing all the work that the electrical manufacturer needs in his publicity campaign. Moreover, his results as an investment will show a more valuable return than those obtained for the exorbitant fee of the "famous" artist. In all advertising artistry imitation is rampant. The great business of advertising would not continue if it were otherwise. The electrical manufacturer who is only now on the verge of public advertising has the advantage as a late comer of observing the mistakes which his predecessors have made. In particular let him take warning and not spend money on the "great artist." We do not wish to disparage the efforts of the latter to please his client. We know from what has already been done that the results have been failures and there is little reason to suppose that in the future they will be otherwise.

REFLECTOR SIGNS.

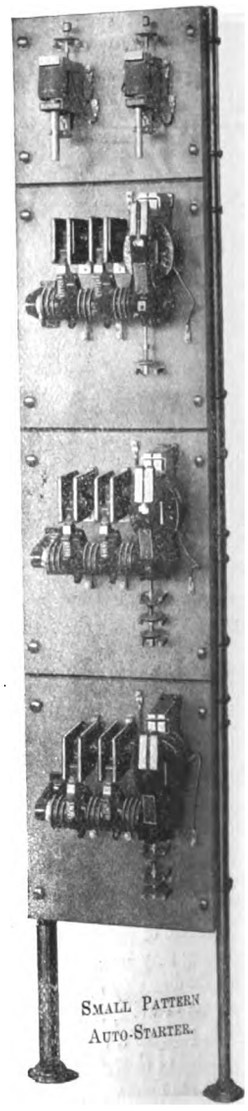
The art of applying modern illuminants to shop window dressing has been given a utilitarian phase by the introduction of advertising signs. These are constructed to serve the double purpose of throwing light upon the goods displayed in the window and illuminating the stencilled lettering at the front of the reflecting surface. Messrs. W. Leonard & Co., Oxford-street, London, W., send us some interesting particulars of their new electric reflecting signs, which include specialities for shop window service. The sign constitutes a simple right angle with a row of lamps suspended in a vertical plane and an opal reflector fronted by a stencilled metal guard, which is also placed vertically in front of the row of lamps. The suspension of the sign is by chain, and we understand that not only is the illuminating effect all that can be desired, but that the tradesman obtains the maximum value from the light by using it to advertise his wares. The sign is very moderate in price and we understand that it is being largely taken up by tradesmen.

A NEW HYDRAULIC GOVERNOR.

We are informed by Mr. Percy Pitman, hydraulic engineer, that his patent governor has been entirely remodelled and fitted with a number of improvements. Among these we may mention a compensating device which prevents over-governing and ensures close speed regulation, and a sensitive spring pendulum which is adjustable for speed and sensitiveness, the parts working on knife edges and the weights enclosed in polished steel casing. There is also a balanced distributing valve having an adjustable sleeve to alter the travel of the servo-motor piston and an automatic self-clearing fitter. The governor is suitable for any type of water wheel on the market. Mr. Pitman will supply fuller details on application.

A.C. AUTO-STARTERS.

The contactor type of motor starter for induction motors is only of recent development, the radial or drum type having previously been used. The advantages of the independent contactor pattern will be apparent from a glance at the accompanying illustration, which depicts a new pattern of automatic starter, manufactured by the British Thomson-Houston Co. The capacities of these starters range from 1 to 300 H.P. and they are suitable for circuits having voltages from 110 to 550. We understand from a recently issued list (No. 302) that this type of starter has been designed for motor-driven pumps, air compressors, &c., which are required to be started and stopped automatically in accordance with the variation of air pressure or water level, as the case may be.



SMALL PATTERN AUTO-STARTER.

The equipment is made up of two-current limit relays, a double-pole main line contactor and a number of double-pole contactors for notching out the rotor resistance. The number of the latter will depend upon the size of the motor and the percentage of full load torque required at starting. The current relays are electrically interlocked with the contactors in such a way that they control the rate of acceleration without the use of dashpots. It is impossible for the motor to be switched in circuit without all resistance being inserted. We understand that the contactors themselves have been specially designed with a view to eliminating noise. Not infrequently switches of this class are apt to be very clattery and may constitute a nuisance.

In the operation of the controller a small switch is utilised for energising the coil of the opening and closing switch. If this small switch has been put in the automatic features of the controller come into operation. This small master switch can also be opened and closed by tappets which will be moved by a tank float or by the up and down motion of a hydraulic accumulator. In the case of vacuum or compressed air systems the switch is dispensed with and the opening and closing of the contactor switch is put in and out of circuit by the contacts of a pressure or vacuum governor.

The controller is offered in a variety of sizes, and we would refer interested readers to the British Thomson-Houston Co. for these particulars.

From the same source we have received lists No. 300 and 301 which respectively deal with B.T.H. alternating-current high torque house pattern watt-hour meters and B29 controllers.

TIMBER PRESERVING.

A successful demonstration of the Rüping process of timber preservation was made at Richd. Wade, Sons & Co.'s works on Tuesday last. Various kinds and shapes of timber were selected for the experiment—redwood, poles, timbers, sleepers, fencing and paving blocks, and whitewood battens and boards. These were all weighed and measured, and then sealed up in the cylinder, where they were subjected to an air pressure of 50 lb. per sq. in. The cylinder was then filled with creosote, whilst the air pressure was maintained. Then a pressure of 80 lb. per sq. in. was put on, after which the pressure was released and the cylinder opened, when the timber was taken out and re-weighed, showing the amount of oil remaining in it. Various pieces of the wood were cross-cut and showed a remarkable penetration of the oil, nearly to the centre; which we are told is impossible in the old method, except at a great cost. The same applied to the whitewood, into which we believe it used to be considered impossible to inject the oil. The extreme cleanliness of the wood was very noticeable, it being quite dry and clean to handle and not dirty and clogged with oil such as one usually associates with creosoted wood. This should render it very valuable where its dirtiness from the old method had precluded its use.

There was a very representative gathering at the demonstration, and the guests were afterwards entertained to lunch in the works. There are at present plants in the world, either specially erected for, or altered to suit the Rüping process, capable of doing over 38,000,000 sleepers, 9 ft. 10 by 5, by this process. The Santa Fé Railway Co., in America, are one of the largest users, and they say the sleepers creosoted by this process have given every satisfaction. The German Government has also adopted the process for all the German railways and telegraphs; also Italy. Messrs. Wade have also plant for Burnettising timber by the well-known process invented by Sir Wm. Burnett which the English Post Office have used for many years, and is eminently suitable for indoor use, also in ships, &c.

THE NEW BRIMSDOWN LIST.

The trade has been so repeatedly requested by the makers of Brimsdown lamps to "see things in a better light" that they will be prepared, with the issue of the Brimsdown list, to impress this necessity upon their customers. The Brimsdown slogan, like the Brimsdown lamp, may be said to have caught on if the new catalogue is anything to go by. The copy before us shows it to be the product of considerable thought and care with one eye on effect and the other on utility. We must compliment the company on the cover. It conveys an abundance of information at a glance. The composite pictures of the Brimsdown works on the second page are clear and convincing. There can be no mistaking the fact that lamps are in process of manufacture. The lamps listed, priced and illustrated cover the complete range from the smallest train-lighting lamp to those of 1,000 c.p., through the usual gamut of voltages and candle-powers. The tables of prices contain useful columns which British and Hefner candle-power are compared side by side. The efficiency of the Brimsdown lamp is 1·12 watts per British and 1 watt per Hefner candle-power. Copies of the list will be forwarded on application to the sales department, Brimsdown Lamp Works, Kingsway House, London, W.C.

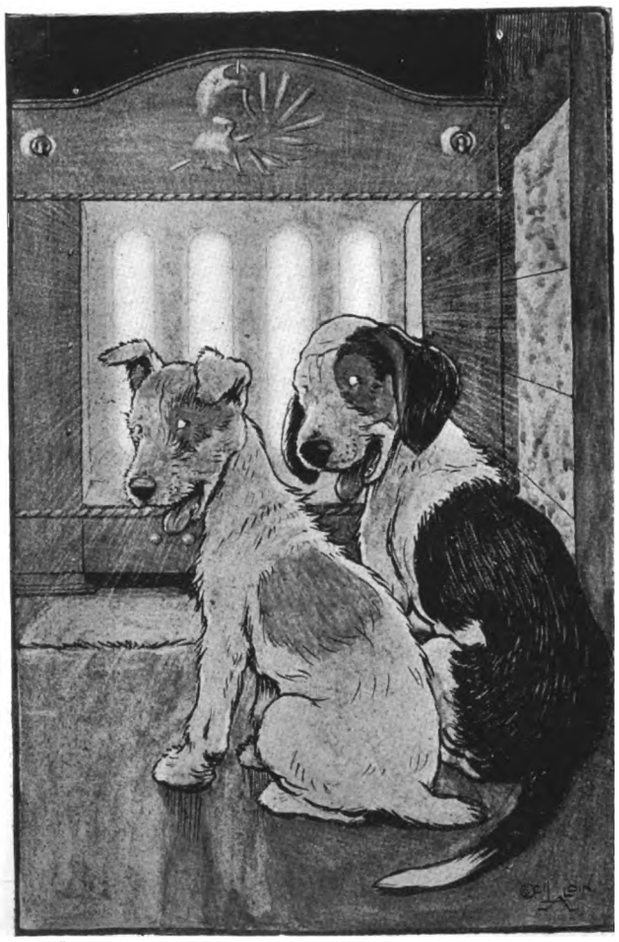
"LOVE ME, LOVE MY DOG."

The Electricity Supply Publicity Committee has got Mr. Cecil Aldin to design them a cover for their new heating and



"SMILE, PUPPY, SMILE!"

radiator literature. Mr. Renwick has kindly favoured us with an illustration of Mr. Aldin's effort, and this we reproduce herewith. As our readers are doubtless aware, Mr. Cecil Aldin has made a name for himself as an artist of hunting scenes and dogs, consequently he is able to make the puppies in the picture turn for a moment from the charms of the electric radiator to smile their canine contentment. Doubtless, as a result of the distribution of this little picture, there will be a big demand for electric radiators among ladies who lavish money on pe animals of all kinds.

AMERICAN ADVERTISING METHODS.

We have received the following letter on the above subject and publish it as a matter of interest :—

A perusal of the article "American Advertising Methods" in your last issue produced a feeling that a damper had been thrown over the enterprise of British advertisers, whose increasing interest in advertising during the past few years has resulted in so marked an improvement. I am not an American, neither have I been to America. But, seeing it is the most progressive country in the matter of advertising, I admire it for that. Had this distinction belonged to any other country my esteem would have been none the less. If any country, by specialised study, gained more enlightenment on a certain subject, and found its application to business highly successful, surely we should not refuse to consider whether these improved methods, either in part or whole, could be applied to our advancement just because they happened to originate in Germany, France or America. I agree that much good money has found its way into the accommodating pockets of the daily newspaper proprietor without producing that which it was intended to produce. But instead of attributing this to American advertising, let us put it down to a misconceived and ultra-aggressive policy.

That circulars, leaflets and other business literature sent through the post are unwelcome to the average Britisher is largely due to their often uninteresting get-up and cheap appearance. Instead of exciting interest they irritate. To be in any way successful, advertising matter of this nature should embody an original idea that will at once attract the attention and excite the curiosity of the recipient. His first impression must be one of inquisitive interest, or, preferably, admiration at its cleverness. Either will invariably lead to a careful perusal, if the story is crisp and well told. I would say—rather than warn the English manufacturer against American advertising methods—suggest that he makes a careful study of them. If, after careful study, any of these so-called American methods seem worthy, let prompt adoption add yet another tribute to his remarkable judgment.

Yours faithfully,
MARCUS HEBER SMITH.
Pp. A. J. GREENLY.

"TANTASHADES."

The metal lamp is responsible for a new design of lamp shade. The old carbon lamp did not lend itself to the pear-drop type of shade, being too short in the neck and too round in the neck. The metal lamp is built on more graceful lines and the shade which clothes its brilliance with a greater beauty must be shaped in keeping with it. Siemens Bros. Dynamo Works have kept the necessity well to the fore and their latest list provides a selection in glassware which would be difficult to beat. The shapes are as varied as the pebbles on the beach. In particular the bead shades should attract attention. They are offered in many different shades, colours and designs. A bead shade might almost be described as "a thing of beauty and a joy for ever."

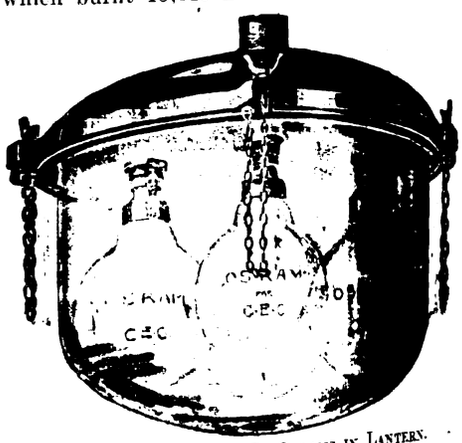
HIGH-CANDLE OSRAMS.

The latest list from the General Electric Co. is devoted to arguments and practical examples of the high candle power Osram lamp. The cover of the booklet is attractive to the eye and in keeping with the contents of the publication. The opening page is occupied by a cartoon from our contemporary the "Electrical Times," which represents the flame arc lamp turning away from the remains of a contest with the incandescent gas mantle to view the challenge of the high candle power Osram lamp, which is represented as a diminutive David throwing down the gage to a giant flame lamp. This cartoon is significant of the future. It will give pause to many a tradesman and contractor who is considering the use of the arc lamp and comparing its value as an illuminant with the high candle power metal lamp. The publication to which we refer and of which an advance copy is before us is mainly devoted to a comparison of the high candle power Osram lamp with the arc lamp and it gives in addition a considerable number of representative installations of Osram lamps for the illumination of every conceivable kind of public place—railway stations, main and side streets, circuses, cinematograph theatres, skating rinks, bowling greens, shops, warehouses, factories, &c. The arguments in favour of the high candle power metal lamp are practically irrefutable, and we anticipate that they will appeal to both the contractor and the light user alike. While it would be incorrect to state that the arc lamp is doomed, it is becoming more and more apparent that the choice of light units for open spaces in the immediate future will rest upon either the flame arc or high candle power metal lamps.

The sizes of the high candle power Osram lamp go up from 100 to 1,000 c.p. units and they are suitable for voltages from 100 to 260. The energy consumption is in the neighbourhood of 1·2 watts per British candle, and this should be sufficiently good to satisfy the requirements of any user. The life of the lamp is also on the high side, though of course the lowest lamp which burnt 15,643 hours at the Stafford Corporation



GROUP OF HIGH C.P. OSRAMS IN LANTERN.

Electricity Works is, fortunately for the lamp makers, the exception rather than the rule.

In the application of these high candle power lamps for practical purposes special lanterns are offered by the General Electrical Co. which will contain one or a group of lamps. The circumstances will of course govern the number of lamps employed. For shop window lighting the grouping of the high candle power lamps appears to be favoured, whereas for open spaces and streets the higher candle power units are employed singly.

THE ELECTRICIAN COMMERCIAL AND INDUSTRIAL SUPPLEMENT.

C. & I. Supplement No. 102.] SEPTEMBER 15, 1911. [Gratis to Subscribers.

Olympia Report.

During the Electrical Exhibition we shall enlarge the pages of the Commercial and Industrial Supplement in order adequately to describe the Exhibits. We have already addressed letters to manufacturers asking for details of the specialities they are showing. Will those Exhibitors who have not replied kindly send *Matter and Blocks* in to us at once.

We are at Stand 180.

GAS AT OLYMPIA.

We extend a cordial invitation to all users and advocates of gas to the Electrical Exhibition at Olympia next week. In particular do we hope that the editor of the "Journal of Gas Lighting" and the writer of the Electricity Supply Memoranda in that garrulous publication will honour the exhibition with their presence. Our own stand number is 180, and if our contemporary will be good enough to make a note of this and look in on us either before or after a round of the exhibits we will gladly administer to his bodily comforts. Would that we might assist him in the preparation of his copy! We know that every effort will be made to bring gas consumers to the exhibition. Manufacturers, contractors and electricity supply authorities will, we are sure, have taken steps to make the exhibition known among this class of prospective consumer. Of course, there are great numbers of gas users who will come both out of curiosity and the natural desire to find something better than they already have. Even our friends of the "Journal of Gas Lighting" would not wish these seekers after light to be debarred from attending at Olympia.

The contemporary referred to above has recently been worried about certain facts regarding the Tricity cooker, and instead of applying direct to the makers of this effective and efficient device asked an explanation of us. We now beg leave to ask our contemporary why it does not organise a gas exhibition at Olympia. In the stuffy sanctity of its own office it can inveigh against electric lighting, heating and power with an amount of energy which might be better displayed in other directions. With a show at Olympia, where there would be plenty of space to fill with burnt gas fumes, the public would have the deciding voice in those matters upon which our contemporary feels itself able to speak with such authority.

ELECTRIC WATER HEATERS.

We have been supplied with particulars of an interesting type of electric water heater which is intended for use in the household. It is of the geyser type in that the water is delivered hot as soon as it is turned on. The heater is a porcelain tube which is packed for the greater part of its length with carbon granules. The two ends are stopped by a special perforated carbon disc, which will allow passage of water but keeps the granules in position. Arrangements are made for passing a current through the granules so that they offer a high resistance and quickly attain a high temperature, which is, however, immediately conveyed to the water which is kept constantly passing through. It is claimed that any desired temperature can be obtained from the cold-water supply in 5 seconds. There is no radiation loss. The water is heated only as used. Consequently, electrical energy is economised. Hot and cold water can be obtained from the same tap. The device can be fitted to any cold-water supply in a few moments. It is also stated that the water is sterilised in passing through the heater. The makers of the device are Messrs. Electric Water Heaters (Ltd.), Gordon-street, Glasgow. It is intended to introduce the device for general purposes, and we understand that it is likely to be fitted to liners or large ships in which there is a supply of electricity available. The energy consumption is either 3 or 6 units for 25 or 50 gallons per hour.

"R.R." CARBONS.

A great variety of carbons for electrical purposes is made by Messrs. Rylander & Rudolphs, Henriksdal, Sweden. We understand that this firm has been established nearly 30 years. Their agents over here are Messrs. James McMillan & Co., Surrey-street, Strand, London, W.C., and they have sent us a very complete catalogue of "R.R" carbons. The list also contains particulars of "R.R." wet batteries and dry cells. The wet batteries are offered in a considerable variety of sizes and shapes and are intended for special use on different kinds of circuits. The dry cells are also made in a large number of different sizes. There is a section in the catalogue devoted to carbon brushes, and here again the products of the company are shown to cover a wide range of shapes and styles. There are some useful notes on the treatment of dynamo brushes at the end of this section. Details are also given of carbon packing rings for steam turbines, these being offered in different radii. One of the most striking portions of the list is that devoted to carbons for telegraphs and telephones. It is almost bewildering to look through the pages in which the different shapes of microphone carbons are illustrated. The list concludes with particulars of carbon shot and granules and special carbons for lightning arresters.

FRANCO SIGNS.

The Electrical Exhibition will be a striking example of what can be done with electric lamps and electric lighting in connection with signs. Practically every stand of any importance will be surmounted by some illuminated electrical device. There are, of course, many admirable examples of electric signs to be met with in the streets of London and also in the provinces. In London especially we notice a form of sign of which a typical example is illustrated herewith. It is made up of a combination of seasoned hard wood into which a number of

FRANCO CHANGING SIGN IN LONDON.

small watertight porcelain holders are fitted. These holders carry miniature lamps of 1 to 2 c.p. equally spaced in the centre of either the letter or the particular design which is to be illuminated. The lamps are wired in series parallel groups and can be connected to any of the standard circuits. We understand that seven 12 in. letters require only ½ unit an hour. The lamps are quite suitable for use in connection with ordinary flashers or time switches. Letters varying in size from 6 in. to 18 in. in height are provided with a single row of lamps, from 19 in. to 36 in. a double row of lamps is employed. Readers who are interested in a sign of this kind for use at Olympia should apply to the Franco-British Electrical Co., Oxford-street, London, W., for further details.

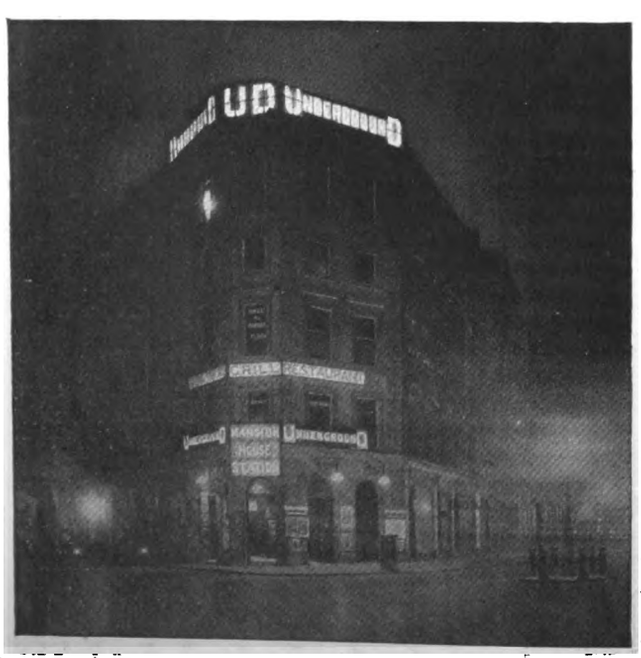
"TILLING-STEVENS" PETROL-ELECTRIC OMNIBUSES.

As a result of the successful running of the new "Tilling-Stevens" petrol-electric omnibuses in London service, Messrs. Tilling have decided to adopt that type for all their future omnibuses and are constructing a fleet to replace their present horse-drawn vehicles. Messrs. Tilling have designed the chassis and body, which are being built at their works at Peckham, but the electrical transmission is supplied by Messrs. W. A. Stevens, of Maidstone. An agreement has been entered into between the two companies in which Messrs. Tilling have secured the sole rights of use and sale of the "Stevens" patent electrical transmission for use in omnibuses and mail vans in the Metropolitan police area, Messrs. Stevens to have the sole rights of manufacture and sale of the complete "Tilling-Stevens" petrol-electric chassis outside the Metropolitan area, and also inside the area for vehicles other than omnibuses or mail vans. The same construction will be adopted in the chassis for use either inside or outside London. The "Tilling-Stevens" petrol-electric vehicles are the result of exhaustive experiments carried over a period of four years under public service conditions in London. The first vehicle, which is still in service in excellent condition, has run over 120,000 miles. As the new vehicle has been designed by the oldest established motor omnibus company in London to meet the latest requirements of the Metropolitan Police, it possesses all the essential qualifications for success, and its extreme silence, smooth running, flexibility and ease of control, together with low cost of upkeep due to the substitution of a flexible electrical transmission for the gear box, should appeal to the travelling public as well as to the operating engineer.

OSRAM LIGHTING IN LONDON.



ONE OF THE FINEST EXAMPLES OF SIGN LIGHTING WITH METAL LAMPS TO BE SEEN IN LONDON.

TWO-POINT LIGHT CONTROL.

What can be more exasperating than to find in a bedroom that control of the light is obtainable at the door only, this necessitating getting into bed in the dark, and having to get out of bed before light can be obtained again. It is not an uncommon occurrence to find houses where the only switch control of the hall and staircase light is provided at the front door, the lack of control from the upper floor necessitating the use of the time-honoured candle to go upstairs to bed by or when descending again during the night. These are but two cases, and many others might be cited. Had greater conveniences been provided the "unsatisfied consumer" would have been a satisfied one and his installation would prove a good advertisement for electric lighting.

When noticing these weak points in his installation he interviews a contractor to have an improvement made, but is usually informed that the alteration will mean pulling the walls about and upsetting the decorations, &c. Consequently the desired addition is seldom effected or else postponed for attention when the next decoration upheaval takes place, he, mean-

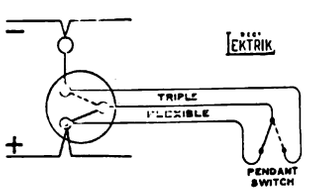


DIAGRAM OF CONNECTIONS.

while, having to make shift with the installation as it stands. It is a simple matter, so Messrs. A. P. Lundberg inform us, to convert the present single-way switch control to that giving control from two points, without any disturbance of the wiring. The conversion simply involves the substitution of a two-way surface switch for the single-way one.

A hole is bored in the wood block and a triple flexible led off from the switch on porcelain buttons, or through insulated screw eyes, to the desired extension point, consisting of a two-way pear switch for bedroom use or one of surface pattern for ordinary use. The simplicity of the adaptation is clearly shown in the above diagram, where it will be noticed that the leads are not interfered with in any way when making the change, and that, contrary to usual custom, the "common" terminals of the two two-way switches are interconnected.

To leave the switch point as it was originally is a simple matter, the two-way switch being made to act as a single-way one by short-circuiting two of the terminals, the flexible and extension switch being disconnected. This provides for the case of the obstinate landlord who requires the installation left as it was found. This simple method, if commonly known, would assist in providing the contractor with some genuine friends amongst his clients, whose recommendations would extend business in the neighbourhood.

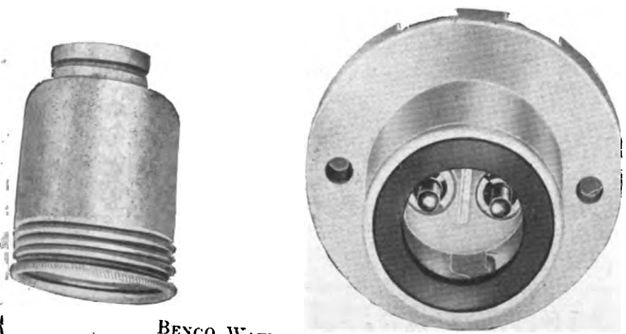
LARGE PRESSURE FILTER ORDER.

The Sheffield Corporation Waterworks Department have just placed a contract for 32 patent mechanical pressure filters and auxiliary plant, capable of dealing with a flow of 6,000,000 gallons per day, with the well-known firm of Mather & Platt (Ltd.), of Manchester. This firm are to be again congratulated upon securing this order, which follows so closely upon the large order they were recently successful in securing from the Ashton, Stalybridge and Dukinfield District Water Board.

BENJAMIN SPECIALITIES.

The Benjamin Electric (Ltd.) has issued several new lists which contain particulars of some of their recent specialities. List No. 42 is devoted to special lampholders, which are in-



Benco Watertight Holder.

nded for use in connection with shop window illumination. everal of these holders are weather-proof, and we illustrate a attern which is all china and which is suitable for mounting strips, borders, ceiling blocks or casings. Moisture is prented from entering the holder by a specially fixed rubber ring, which makes an effective joint with the lamp cap. In list No. 41 particular emphasis is laid upon the company's specialities in reflectors for shop-window and show-case lighting. Some of these reflectors are supplied without lamps, others are fitted with the Benco patent lampholder, which secures the lamp in a horizontal position within the trough of the reflector. The shop-case reflectors are suitable for standing lightly on the glass-work at the top of the case and throwing the accentuated rays of the lamp on to the goods in the case below. The Benjamin Electric, at 117, Victoria-street, London, S.W., are willing to advise intending users of electric light as to the best method of utilising their special reflector.

OLYMPICS.

Will Mr. Hirst buy the Crystal Palace and present it to the N.E.M.A. for a permanent electrical exhibition?

Why cannot the editor of the "Journal of Gas Lighting" be compelled to open the exhibition?

Will there be a strike among the bar attendants?

Will non-exhibiting canvassers be frog-marched out of the exhibition?

Can the Executive prevent the manufacture of ozone while the band is playing?

Will Sir Wm. Preece be allowed to mention T—— R—— at the inaugural banquet?

Will the new N.E.M.A. secretary give a dinner to the disappointed applicants for the post?

"AFTER SUNDOWN, BRIMSDOWN."

A good slogan will ofttimes bring business in making a commodity known to the public in a happy kind of way. The above is the latest addition to the list of electrical slogans. It is both apt and easy and rolls readily off the tongue. We find it embodied in a pithy little folder which the Brimsdown Lamp Works are now sending out with this season's literature. It tells of the sizes of Brimsdown lamps and their prices and candle-power, British and Hefner. Actually it is something of a pocket edition of the larger Brimsdown list which we reviewed last week. Incidentally, we may say, that in that list particulars are given of the numbers of the holophane shades which may be used with Brimsdown lamps of various sizes.

SMALL SIZE REPRODUCTION OF BRIMSDOWN CIRCULAR.

E.P.S. MINER'S LAMPS.

There have always been difficulties in the way of the introduction of electric battery lamps for mines and collieries. We have been over a large colliery in the North of England in which all the batteries are made at the pit bank, in fact, everything is manufactured *in situ* except the lamps. Singularly enough, in this instance the management have been unable to get a satisfactory metal lamp which would stand up to the rough handling to which all miner's lamps are subjected. The E.P.S. Co. have sent us particulars of their miner's lamps, which are made in a number of patterns of different capacities. It is claimed for these lamps that they have a high efficiency and a powerful working light can be obtained. Three patterns of lamps are fitted in enamelled metal outer cases. The burning hours range from 15 to 30 hours. It is stated that no cleaning or trimming is needed. In a pattern known as the "up and down" lamp, the light is thrown on the ground and on the roof.

ENAMELLED COPPER WIRE.

A special sheet (No. 34A) is being issued by W. F. Dennis & Co., 49, Queen Victoria-street, London, E.C., giving prices and particulars of F. & G. black enamelled H.C. copper wire. This is offered in sizes ranging from 14 to 42 S.W.G., and can be supplied on reels which vary in weight according to the size of the wire from ½ lb. to 28 lb. per reel. The wire is delivered in lots of 2 cwt. and over. We understand that the enamel has a high insulation resistance, and that it has considerable heat and moisture-resisting properties. Instrument makers and switchgear manufacturers, also arc lamp makers, will doubtless be interested in this new leaflet.

FILLING IN THE VALLEYS BETWEEN THE PEAKS.

J. & P. SWITCHGEAR.

A comprehensive switch and instrument list has been prepared by Messrs. Johnson & Phillips, and it appears to us to be one of the most complete publications of its kind that has been sent out in recent manufacturing literature. It comprises 72 pages, which are replete with information on the subject of switches of all patterns and switchgear accessories. The line of oil switches listed is very complete and covers types suitable for pressures from 600 to 30,000 volts. There is a standard line of these switches made for the control of three-phase circuits. In the H.T. switchgear section there are details given of current and potential transformers, isolating switches, choking coils, lightning arresters and limiting resistances. These have all been carefully standardised, and we understand can be delivered at short notice. The list also gives details of motor starters for A.C. slip-ring motors and these starters can be supplied with automatic overload and no-load features. In the same section star-mesh starters are described and priced. Interesting details are included of A.C. liquid motor-starters. There is a considerable portion of the catalogue devoted to D.C. motor-starters. The list is concluded with illustrations of typical assembled switchboards. One of these was designed for controlling a large pumping plant.

NEW THINGS YOU MUST SEE AT OLYMPIA.

Our readers who are interested in the novelties at the Exhibition, and by these we mean things which will "first see the light" of Olympia, should make notes of the following items:—

New Osram Lamp 200 v. 16 c.p. General Electric Co. Stands 103-112.

Henley's New Wiring System. Stand Nos. 178, 185.

Barbour's 50 kw. Homopolar Generator. Stand Nos. 27, 34.

B. T.-H. Mazda Wire Lamp. Stand Nos. 124, 135, 297.

Buller's 100,000-volt Disc Insulators. Stand Nos. 118, 141.

W. F. Dennis' New Twin Lead-covered Wire. Stand No. 293, Gallery.

New Compression Motor Starter and Electric Cooking Apparatus. Ferranti Limited. Stand Nos. 102, 113.

Dugdill's "Constellum" Adjustable Fitting. Stand No. 238.

Quick Break Two-way Thermo-Blink Sign Flasher. Sun Electrical Co. Stand Nos. 104, 111.

Hope's "Bimetal" Fuse Wire, stands 90 per cent. fusing current before blowing. Parmiter, Hope & Sugden (Stand Nos. 81, 91) and Simplex Conduits (Stand Nos. 148, 163).

"The Ducter." Evershed & Vignoles. Stand No. 168.

C.T.S. (Cab-tyre Sheathing) Conductors of St. Helen's Cable & Rubber Co. Stand Nos. 196, 219. Callenders.

Gray's Electric Oven. Bertram Thomas. Stand Nos. 22, 39.

The Cross Engine. Westinghouse Brake Co. Stand No. 6.

Bruston Automatic Electric Light Plant. R. A. Lister. Stand Nos. 11, 12.

20,000-volt Ironclad Switch Panel. A. Reyrolle & Co. Stand No. 147.

Preliminary Description of Exhibits, p. 177.

Map Plan of Olympia and Classified List of Exhibits and Stand Nos. on pp. 178, 179.

A HOMOPOLAR GENERATOR.

On Stands 27-34 Messrs. Homopolar Machines are showing a 50 kw. 100-volt direct-current turbo-generator on the homopolar principle (Fig. 1). In this the armature flux never changes sign, so that there is no core loss. Fig. 2 shows a section (not to scale) through the machine on the centre line. The magnetic circuit is double, *a a* and *b b* being the two portions, each of which forms one end pole. Each pole extends

completely round the armature with no change of sign. There is thus no iron loss. R is the rotating part, or armature. M is the fixed part, or frame. E E′ are the exciting coils, which are placed directly round each air-gap, so that leakage is reduced to a negligible figure. The smallness of the gap is limited only by mechanical considerations, consequently the field copper loss is small. The conductors C in which the volts are generated lie in micanite tubes in tunnels in the armature, under the central pole, and are connected at each end to slip rings D from which the current is collected.

The rotor has a strong steel shaft S, and a high permeability steel core P. On this are mounted the slip rings D, and also the rings GG forming the end poles. In the diagram the centre pole of the rotor is shown solid with the core, and the end poles are solid rings. While this is not necessary electrically it is sometimes convenient mechanically to build these up of laminations. Bolts B pass from one end of the rotor to the other and are insultated by mica tubes like the armature conductors, and hold the slip rings and pole rings solidily in position. There are mica washers between the rings; thus mica is the only insulating material used in the rotor. The rotor has a periphery of great strength, and it is claimed that the construction adopted renders the machine mechanically sound. The frame M of the machine consists of three castings, a large one comprising the central pole and the yokes, and two smaller ones forming the end poles and carrying the bearing brackets. The frame carries stationary conductors, which connect the armature conductors in series.

The slip rings are grooved, and in the grooves lie the brushes AA (Fig. 3), which consist of a flexible copper core wound with an armouring. The latter, though slightly diminishing the flexibility, both protects the core from wear and is found by experience to make better contact with the slip ring than any other form of brush. The brush is held in place round the ring by springs BB, the tension of which is regulated by the screw and nut K, while the current is led away by the flexible leads L to the stationary conductors. Appended are the leading dimensions and particulars of the machine, from which it will be seen that it is of extremely compact dimensions. The shortness of the distance between bearings is especially remarkable, and should lead to freedom from vibration troubles.

DATA OF THE MACHINE EXHIBITED AT OLYMPIA.
50 *kw.*, 100 *volts*, 500 *amperes*, 3,500 *revs. per. min.*

Total length between bearings	29½ in.
Height of frame	28½ in.
Width of frame	28 in.
Diameter of rotor	14½ in.
Peripheral velocity	12,800 ft. per min.
Field amperes	5
Number of conductors	12
Width of each slip ring	½ in.
Length axially of centre pole	6 in.
Length of each end pole	3½ in.

The generator is belt-driven by an induction motor, the speed of which can be regulated by a patent regulator lent by the Electrical Apparatus Co., Ltd. This regulator gives infinitely gradual control of the speed, but has no water resistance and no contacts, the operation being entirely electromagnetic.

Messrs. Homopolar Machines also show an interesting model on the Homopolar principle in which all the iron of the ma-

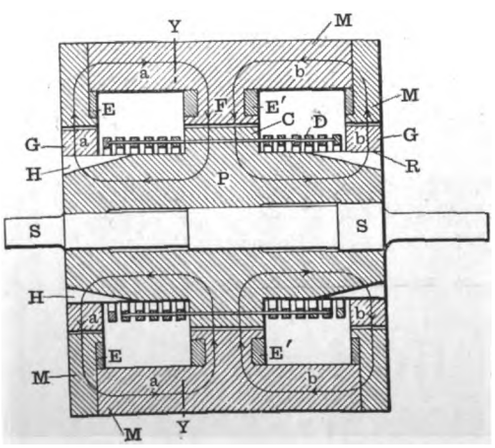

FIG. 2.—SECTION THROUGH HOMOPOLAR GENERATOR.

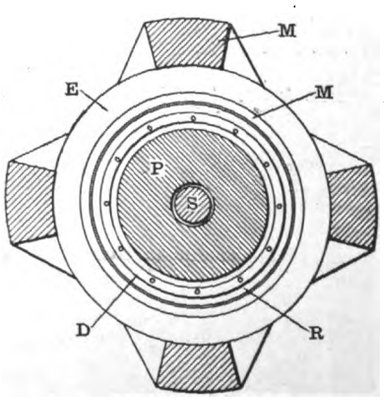

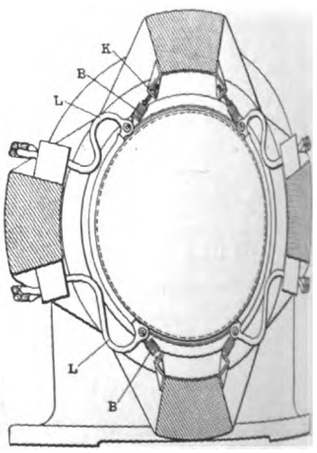

FIG. 3.—VIEW OF BRUSHES.

netic circuit and the field coil revolve, as well as the armature, the brushes only being stationary. This was invented by Mr. R. H. Barbour, managing director of Messrs. Homopolar Machines, as a self-driving flywheel for a gyroscope, where the weight of the stationary portions of the machines must be reduced to a minimum. This machine is described in detail in the columns of THE ELECTRICIAN this week.

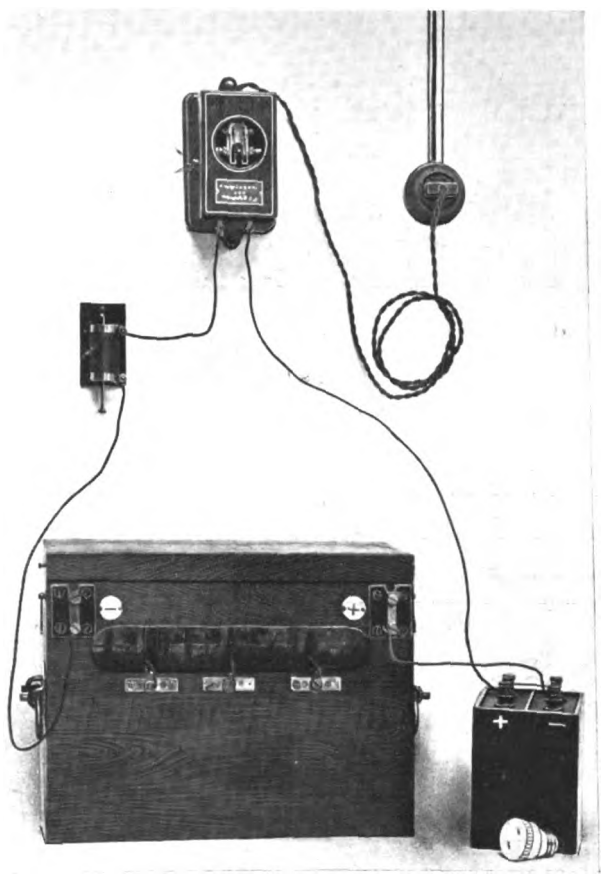
A VIBRATORY RECTIFIER.

When Mr. Ferranti introduced his famous rotating rectifier for the supply of an interrupted but uni-directional current for arc lighting, hopes were entertained by some engineers of replacing the rotating mechanism by some vibratory form of apparatus. Of recent years the problem has again been tackled, and mainly with the idea of producing a device for the charging of accumulators from A.C. circuits. The Adnil Electric Co. is issuing a pamphlet describing a vibratory rectifier which has been developed and successfully applied for the last-mentioned purpose. The rectifier is, of course, simplicity itself. It comprises a transformer in which the stray field is utilised to actuate an armature which moves the contact system provided for breaking the circuit at the zero point on the



Adnil Rectifier Charging Accumulators.

A.C. curve. By this means a rectified current is produced. We understand that perfectly synchronous working of the contacts is assured. It is also stated that the efficiency on load and open circuit is practically that of a transformer of similar output. Adjusting screws are provided by which the vibrating contacts can be altered for various frequencies. It will be noted from the illustration that the rectifier is complete in itself and has no auxiliary apparatus. For accumulator charging the device is extremely economical. With energy at 3½d. per unit a 6-volt 25 ampere-hour capacity battery will cost 2s. to charge when using resistances. With a rectifier the cost would only be 1½d. The rectifier is offered in four sizes for voltages between 100 and 250 and capacities from 1·2 to 2·2 amperes charging current. If a condenser is used small motors and alarms, &c., can be put in circuit with the rectifier.

OSRAM·LAMPS

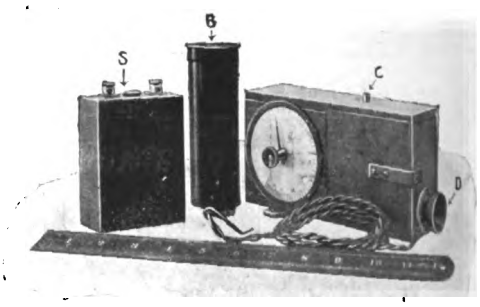
THE LUXOMETER.

The widespread interest now being taken in the measurement of illumination, both interior and exterior, has led to a demand for an inexpensive instrument, which, while not claiming to be a standard in the same respects as the Trotter portable photometer could yet be relied upon to give results of ample accuracy for all purposes, and which was, at the same time, not only light and thoroughly portable, but above all easy to use.

In the past, portable photometers have been looked upon somewhat as luxuries, to be possessed only by the larger undertakings, and it is with the object of dispelling this erroneous idea that the Luxometer has been placed on the market. For the comparison of the candle-powers of various forms of lamp, or for the measurement of the illumination of any surface, or that of a room in which it is desired to improve the lighting, as well as for the determination of the efficiency of daylight illumination, and, in fact, for general use by electrical or gas engineers, officers of health, architects, &c., the Luxometer is particularly suitable. Apart from its low cost, the instrument embodies the following features:—Extreme compactness. This is strikingly shown in Fig. 1 which shows the complete outfit, including the Luxometer (C), Battery (S), and Daylight attachment (B). It may be added that the weight is only 11 lb.

Long open scale. The scale is about 6 in. long and in standard instruments is graduated up to 10 or 20 foot candles, as preferred, with two ranges. It is specially opened out for the lower part so that great accuracy is possible even when measuring feeble illuminations. The scale is direct reading.

When in use the instrument is held in the hand, no stand or other support being required. For transport, both the photo-



General View of Luxometer.

meter and the battery can be carried in the pocket, or they can be supplied fitted in a small leather case with shoulder strap if preferred. Illumination measurements can be made at any angle, irrespective of the colour of the light.

Candle-power measurements can be readily made (also irrespective of the colour of the light).

The surface brightness or intrinsic brilliancy of any surface can be instantly measured by viewing it through the instrument.

The principle upon which this photometer is based is a modification of the well-known Trotter method in which the illumination derived from an electric lamp, contained in the case, is adjusted until it is equal to that to be measured. A pointer moving over a direct reading scale indicates this illumination without any calculation whatever. Of all the standard lamps which have been tried with portable photometers the electric lamp has proved itself to be by far the most satisfactory, and some recent investigations by Mr. A. P. Trotter show conclusively that such a lamp worked off a portable accumulator more than fulfils all requirements.

The cell supplied with the Luxometer is of a special "non-spillable" type contained in a celluloid or ebonite case so that it can be used in any position or carried in the pocket without fear of spilling. It only requires charging at rare intervals, and this can be done at any motor garage.

THE OLYMPIA ELECTRICAL EXHIBITION.

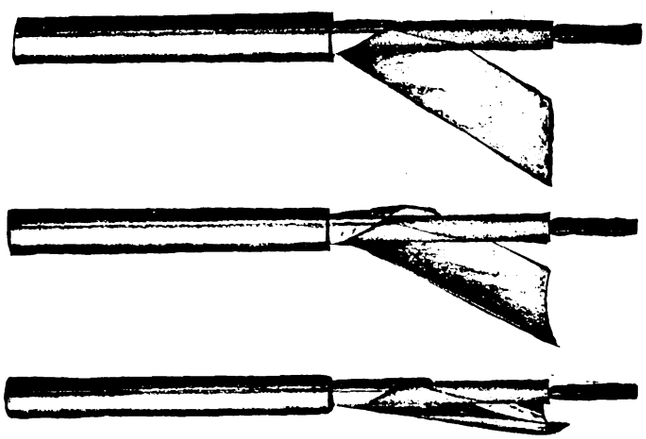
A List of the New Things at Olympia is given on the first page.

The usual complaint about Exhibitions is that they are never ready on the opening day. This indictment cannot be levelled against the Electrical Exhibition which will be opened at Olympia to-morrow. The exhibitors were admitted to the building on Monday week last, the 11th inst., and in the space of a fortnight, which, though it seems long, is in reality all too short, they have done little less than wonders. Several of the stands are fitted out on exceptionally elaborate lines, and will be immediately distinguishable among the many in the body of the hall. With few exceptions the stands are being brilliantly illuminated. Every conceivable kind of lamp and sign has been pressed into service, and the public will be almost dazzled by the persistent abundance of the illumination. We hope they will profit by observing that with such a superfluity of light there is neither smell nor heat. Their imagination may be permitted full play in an attempt to conceive what Olympia would be like under similar conditions with gas!

There are conspicuously few open stands in the Exhibition. By this we mean displays in which there is no attempt to enclose the main portion of the stand with box-like structures which completely obscure the general view of the exhibit. The most noticeable of the open stands is that of Ferranti, Ltd., which has been prepared on quite unusual lines. There is an elaborate woodwork "surround," arranged at a convenient angle, upon which the various smaller products of the company are displayed. Within the space enclosed by this novel border there is room for the display of photographs of many of the company's important installations. The centrepiece of the exhibit is a three-panel extra-high-tension ironclad switchgear and three-phase extra-high-tension solenoid operated switch. Even these have been sunk down below the level of the floor so that they admit of a clear view over the stand. Another open stand is that of the Union Electric Co., which immediately adjoins that of Messrs. Ferranti, and ironclad switchgear is made the centrepiece of this exhibit, the gear being surmounted by arc lamps and a searchlight. Most of the heavy exhibits machinery such as the Brush Electrical Engineering Co., Bruce Peebles, Electromotors, Ltd., Sunderland Forge & Engineering Co., have also stands of the open pattern. The Berry Construction Co. have also an open stand. The majority of the other stands are closed in, mainly on account of the fact that exhibitors require to display fittings, lamps, shades and reflectors which can only be attached to vertical supports or suspended from something in the nature of a roof. The utmost advantage has been taken of this form of stand by most of the exhibitors to render it as artistic and ornate as possible. Here we may specially mention the exhibits of the General Electric Co., the British Thomson-Houston Co., the Siemens pagodas, Henleys, Simplex, the Jandus Arc Lamp and Electric Co., Drake & Gorham, St. James and Allied London Companies and Municipalities, the Sunbeam Lamp Co., and Messrs. Edison & Swan. At the present juncture we cannot enter into full details of the exhibits, because at the time of writing most of the stands are in an incomplete condition. We have, however, been able to gather from a preliminary round of the show what the finished appearance of the stands will be like. We give below a few details of the principal exhibits and particularly of those in which novelties are displayed.

Henley's. (Nos. 178, 185.)

An exceptionally fine and comprehensive display of their products is being made by W. T. Henley's Telegraph Works Co. The stand is one of the largest in the exhibition and is near the centre of the hall on the right-hand side. In particular our readers will be attracted to this stand by a new wiring system which the company is bringing to the notice of the trade for the first time. The essentials of the system are its low first cost, and its economy and adaptability in erection. The system has been introduced with a view to meeting the undoubted demand for an efficient and inexpensive method of wiring domestic premises of moderate rental. From an initial inspection of the system there should be every possibility of the manufacturers' hopes being realised. A single V.I.R. insulated conductor is used and over the insulation is laid a thin spiral of copper tape, finally there is a lead covering over all. This constitutes the conductor. The fitting utilised for ceiling roses, switches, &c., is extremely simple and allows for the ready connection of the outer copper tape and the bringing of the insulated conductor through the wooden block. The conductor is suitable for concentric wiring, and on alternating-current systems there should be a big demand for it



Conductors for Henley's New Wiring System.

The lead covering renders the conductor infinitely flexible and it can be fitted up with ordinary cleats and saddles. We shall fully describe the system in our next issue.

Siemens. (Nos. 179, 184, 206, 209.)

The exhibit of the Siemens Companies (Siemens Bros. & Co. and Siemens Bros. Dynamo Works) is housed in two stands which are attractively built up as Japanese pagodas. The design and arrangement of the stands is such that visitors will have no difficulty in recognising them on sight. The display of apparatus comprises a show of cables and accessories, the well-known O.S. Wiring System and a variety of instruments. An interesting show is being made of electric heating, cooking and power devices. Amongst the latter may be mentioned a 5 H.P. vacuum cleaner with direct-current motor, and also, touching the heavier side, a desk type mining pillar of the draw-out pattern, suitable for voltages up to 3,300. Batteries and testing units are well to the front, and in the region of lighting the famous Tantalum and Onewatt lamps are prominently exhibited, both individually and in conjunction with an elaborate collection of fittings.

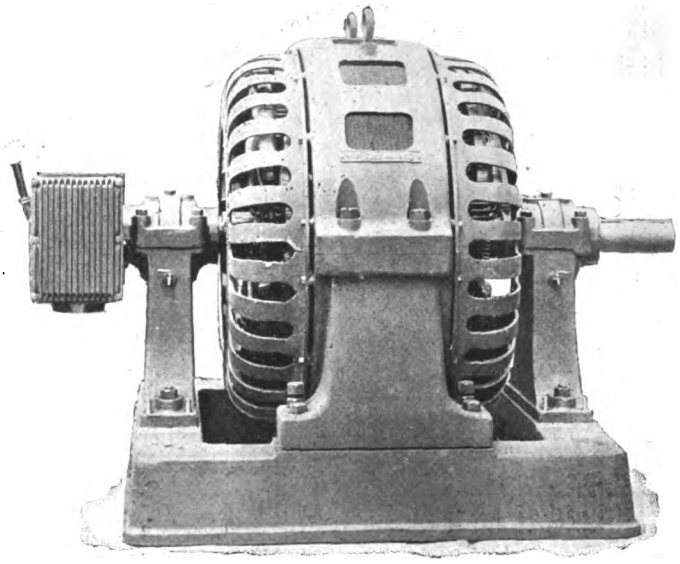
Simplex. (Nos. 148, 163.)

The exhibit of Simplex Conduits, Ltd., should attract attention on account of the neat little interior showroom for fittings which has been erected on the stand. This has been arranged to show fittings to visitors under the only possible conditions and to the best advantage, namely, with the lamps lighted in them. This display will be very largely one demonstrating the advantages of holophane reflectors. The outside of this novel showroom is made use of to display the Simplex conduit system for electric light and power wiring. The collection of signs which have been designed for use in shop windows combining the functions of advertising and illumination, should be specially examined. We may also remind our readers that Simplex Conduits are showing their latest designs in cooking apparatus, also small motors and meters.

Phœnix Dynamo Mfg. Co. and Dorman & Smith. (Nos. 59, 64.)

These companies share a stand not far from the main entrance, on the lefthand side. The first mentioned has a 300 B.H.P. 3,000-volt slip-ring type induction motor operating at 3,000 volts 485 revs. per min. This is suitable for underground haulages, and slip rings are enclosed in flameproof boxes. The Phœnix patent mining



P.D.M. 300 H.P. A.C. MOTOR.

motor, exhibited in the 35 B.H.P. 500-volt pattern, is also a prominent feature on the stand. It is claimed that there is total immunity from fire risk by the use of this motor in mines.

The Dorman & Smith section of the exhibit comprises practically all the switchgear products for which this well-known firm has made itself famous.

Ferranti, Ltd. (Nos. 102, 113.)

As we have already intimated above, the display made by Ferranti, Ltd. is of an exceptionally striking character. The company is making show of a full range of its manufactures. They wish to direct attention to a new direct-current motor starter which has no face plate and only two contacts are utilised in its construction, these being those of the circuit breaker. We understand that there are no metal resistances nor asbestos, only mica being employed, the principal elements of the starter being iron, steel, carbon and mica. There are new designs in time switches and cooking apparatus of all descriptions. The company also make an interesting announcement in regard to their cooking and heating exhibit. This comprises a tin oven mounted on a hotplate, large and small radiators and toaster, single and double heat hotplates and 4 lb. and 6 lb. flat irons. Messrs. Ferranti also have a switchboard in service in the substation supplying energy to the Exhibition, and this doubtless will be inspected with interest.

Johnson & Phillips. (Nos. 123, 136.)

A comprehensive exhibit is being made by this firm and our readers will be specially interested in the magazine "Metroflam" arc lamp. This has been developed from the designs of Mr. J. Brookie and it embodies many interesting features which can be examined in detail at the stand. This lamp burns for 80 hours at each trim and there is no dark interval during the change of the carbons. The lamp enjoys a considerable vogue and is being taken up largely by light users of all descriptions. There is a prominent searchlight display on the stand and in the switchgear section will be found a remote control board, a 3,000-volt board and a quantity of low-tension gear. In the substation which supplies energy to the Exhibition there are also two boards which control the 2,000-volt two-phase supply and the three-phase low-tension supply. The high-tension board is inside the sub-station.

Pope Lamps. (Nos. 207, 208.)

A decidedly novel exhibit is that arranged by Messrs. Pope's Electric Lamp Co. It takes the shape of a lighthouse, which is placed in the centre of the stand and from the upper window there are radiated in four directions particularly solid beams of light, bearing the letters "Pope Lamps" picked out in metal lamps. This is an effective exhibit and will doubtless prove one of the most popular of the attractions. The company manufactures practically every standard type of metal lamp and has arranged to give facilities for the inspection of these to visitors to the stand.

Electromotors, Ltd. (Nos. 126, 133.)

This company is making a comprehensive exhibit of its products on an attractive stand near the centre of the hall. They specially direct attention to the fact that they are makers of dynamo and motors and specialists in the complete electrification of works and factories. The exhibit will be representative of all the company's products in this particular. We may mention specially a 4 kw. 550 revs. per min. steam dynamo for ship lighting, a 20 H.P. 850 revs. per min. type ventilated motor with weather-proof cowl, a 5 cwt. friction hoist and a 30 in. slow-speed propeller fan capable of dealing with 6,900 cubic ft. of air per minute at 450 revs. per min.

"Tricity" Cooker. (Nos. 30, 31, 312.)

The much talked of "Tricity" cooker is being shown on this stand by the Berry Construction Co., and is to be seen in practically all its forms. In conjunction with it are ovens, coffee and water urns, grills, flat irons, saucepans and steamers. We would also call attention to the special chinaware utensils which have been introduced in connection with these cookers. The company has laid itself out to give an adequate demonstration of what can be done with electric cooking, and its efforts in this direction should be appreciated.

Nalder Bros. & Thompson. (Nos. 86, 87.)

Our readers will be able to inspect the display of "N.C.S." instruments, such as voltmeters and ammeters, of both the recording and indicating type, the Ohmer and the "N.C.S." thermal limiter. The latter is a comparatively recent instrument, and is intended for use in the circuits of consumers who pay for energy at so much per lamp per annum.

Westinghouse Cooper-Hewitt Co. (No. 82.)

On this stand will be shown the Westinghouse silica lamps, "the flame arc without carbons." Of interest will be the lamps arranged for alternating-current circuits in conjunction with a special mercury vapour rectifier. This lamp has been found more efficient than the direct-current pattern. The Westinghouse water sterilisers and a large number of special fittings for use with Cooper-Hewitt lamps complete the exhibit.

B.T.-H. Co. (Nos. 124, 135.)

The display made by the B.T.-H. Co. is principally attractive on account of the Mazda drawn-wire lamp. This is the first occasion upon which the lamp has been publicly exhibited, and it should be inspected with considerable interest on that account. The stand has been arranged on extremely novel lines, and is surmounted by a mechanical representation of the company's well-known poster which represents the earth, the sun and the Mazda lamp in juxtaposition, the latter being represented as rivalled by the sun. The company's many other products, such as arc lamps, particularly the Magnetite, calorite irons, Mazdaliers, are effectively grouped on the stand. Photographic illustrations are shown of the company's manufactures in the way of switchgear, turbo-generators, motors, &c.

C. A. Parsons & Co. (Nos. 203, 212.)

The exhibit of this well-known Newcastle firm has been confined to models and photographs of their famous turbo-generators. These are admirable examples of the model maker's art, and clearly serve to depict the excellence of the design of these machines.

Brimsdown Lamps. (Nos. 100, 115.)

The growing popularity of the Brimsdown lamp should secure for it many visitors to the Exhibition. The company's stand has been arranged for the effective display of the Brimsdown (colloid-tungsten) metal lamps which our readers are aware are made for all voltages and candle-powers. We understand that a complete range of illuminating specialities, particularly in the way of shades and reflectors, will be made. The facia of the stand has been outlined with a new pattern of reflector illuminating strip. With these and numerous other attractions the Brimsdown Lamp Works should be able to make its visitors "see things in a better light."

THE STERLING TELEPHONE AND ELECTRIC CO., LTD.
200, UPPER THAMES STREET, LONDON, E.C.

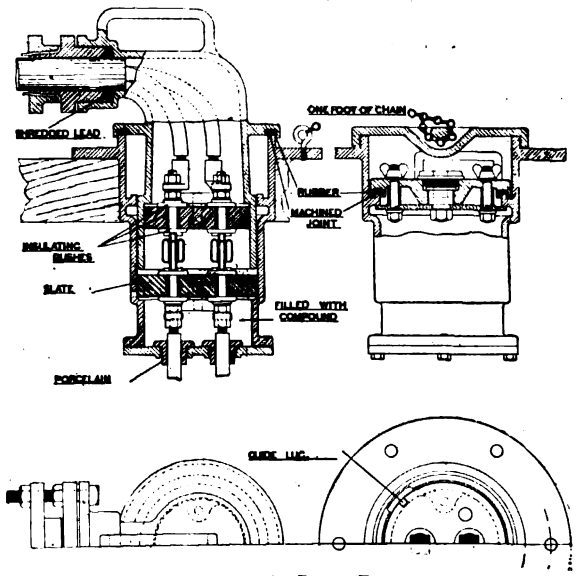
Write for New List No. . . 177.

Sun Electrical Co. (Nos. 104, 111.)

This company's stand is near the centre of the hall and will be found principally attractive on account of its varied display of electrical signs. The company has specialised in these for many years past, and have we understand built up a big business in connection with them. Fittings and accessories of all kinds will also be shown, and electrical contractors, consulting engineers and architects should make a point of inspecting the Kalkos wiring system to which considerable prominence is being given.

Callender's. (Nos. 196, 219.)

Boxes.—The exhibit of Messrs. Callender's Cable & Construction Co., Ltd., consists principally of a collection of various types of electrical and underground junction boxes. The exhibit contains examples of feeder pillars, both lighting and traction, underground network boxes, mining boxes, as well as ordinary service and house-fuse boxes. The combined high and low tension pillar should be noted; when used in conjunction with underground transformer tank, it forms a small transforming station. This should be of great interest to engineers in charge of an extensive district in which alternating-current is supplied. A special colliery iron winding drum is shown of a small size, but these drums are made of full size for high or low tension sinking cable, and for sinkings to 900 ft. in depth



CALLENDER'S PLUG BOX.

Alloys.—The alloys section of this exhibit will also be of interest to engineers. Callender's have already established a considerable reputation for the quality and reliability of these materials. As they are large users of the metals from which their alloys are manufactured, they are in a position to offer alloys of all qualities at low prices. The exhibit consists principally of bronzes and anti-friction white metals.

Kalbitum Paint.—As there is always a demand for a preservative paint for use with ironwork for preventing rust and corrosion, Callender's take the opportunity of this exhibition to bring to the notice of the public their now well-known Kalbitum paint. Free samples of this paint will be sent on application.

Kalanite.—This material is well known to the electrical trade as an insulator of high quality which can be supplied at a low price, and inquiries will be welcomed. It can be moulded or turned, and made up into any shape; it can also be supplied in sheet or rod form.

Electric Batteries.—Callender's also manufacture the "Fors" accumulator for Richard Pape, Ltd., and a further section of the stand is given up to these well-known accumulators. In this description it is not possible to give all the special features of this battery, but it is sufficient to say that its weight and size in proportion to its output is less than any other accumulator on the market, while owing to its design, short-circuiting and the buckling of the plates are absolutely impossible.

Brush. (Nos. 84, 89.)

The exhibit of the Brush Electrical Engineering Co. ranks in the class of "heavy" manufacturers. It comprises a Brush-Parsons combined action and re-action mixed pressure turbine operating at 2,500 revs. per min.; the machine has an output of 400 kw. with high-pressure steam or mixed high and low pressure, and of 300 kw. with low-pressure steam (about 16 lb. per sq. in.), the vacuum being 28 in. A direct-current generator is direct connected to the turbine, and has commutating poles, slotted drum armature, special ventilated commutator and sliding box pattern brush-holders. Adjoining the turbine is a 22·5 kw. steam dynamo designed to run at 650 revs. per min. under 200 lb. pressure. The dynamo is filled with special ball bearings, direct-current and alternating-current motors, travelling pulley blocks, and Gese pulley block and the Marshall hoist, a portable grinder and the collector gear for the Bremen trackless trolley system complete the exhibit.

Western Electric Co. (Nos. 51 and 72).

This exhibit is mainly comprised of telephones and switchboards for large exchanges for operation on both the central battery and magneto systems. The company has done a great deal of work in this direction, and the illustrations of large exchanges equipped with Western electric apparatus should be examined with interest. From the more public point of view, the telephone exchanges for use in hotels, municipal buildings, asylums, hospitals, factories, clubs and commercial houses are of considerable importance, and the examples exhibited are, we understand, up to date in every respect. The largest telephone exhibited is a central battery multiple switchboard with lamp signalling, as installed at the G.P.O. It comprises three two-panel sections with two operators, and immediately adjacent are the main distributing frames, combined meter and relay rack, power board and battery of 11 storage cells. A large hotel switchboard suitable for installations of not more than 240 lines is shown.

WESTERN ELECTRIC INTERCOMMUNICATION TELEPHONE.

This is fitted with eyeball signals. The cordless table switchboards made by the company are also exhibited. These are extremely convenient, and, owing to their simplicity and low maintenance, have been found of immense value in the Colonies and foreign countries. The company's "Westophones" and interphones are also to be inspected. There is an electrical supplies section, in which metal lamps, "Amazon" insulating tape, fibre conduit, line material, fuses, &c., are prominently displayed.

OLYMPIA
ELECTRICAL
EXHIBITION.

General Electric Co. (Nos. 103, 112, 125, 134.)

A wide and comprehensive exhibit, representative of most of the company's manufactures, is being made near the centre of the hall. The exhibit is divided into two stands, one on each side of the central gangway. A considerable portion of it is devoted to Osram lamps and fittings, and a fine display is being made. There is also a good show of the company's heavier products in the way of switchgear, motors, telephone apparatus, tools, &c.

Jandus Arc Lamp & Electric Co. (Nos. 105, 110.)

The attention paid by this company to the regenerative arc lamp, of which they make a speciality, is exemplified in the excellent arrangement of their exhibit. The lamps will be shown burning in special compartments fitted with blue glass fronts, through which the behaviour of the arc can be comfortably examined. The company direct attention to their small consumption lamp, which takes only 250 watts, including line resistance, and gives a candle-power of 1,800 to 2,000 at an angle of about 15 per cent. below the horizontal. The lamp burns 100 hours, and, compared with a 200 c.p. metal lamp, consumes the same energy but emits approximately 10 times the candle-power.

Lancashire Dynamo & Motor Co. (Nos. 122, 137.)

The exhibit of this firm is combined with that of Messrs. Joshua Buckton & Co., and is principally noticeable for the display of a large planer, in which the table is operated by variable-speed direct-current motor, which is arranged by special control gear to speed up the table of the planer on the idle stroke. A representative exhibit of the company's products in direct-current and alternating-current motors is also made.

Sunbeam Lamp Co. (Nos. 55, 68.)

An attractive exhibit has been got together by the Sunbeam Lamp Co. comprising a full range of their electrical fittings and accessories. In particular they wish to call attention to their metal lamps which are made in sizes from the smallest battery lamp to those of 1,000 c.p. The carbon lamp is, of course, not dead yet, though we anticipate at the next Electrical Exhibition it will be displayed rather as a relic than an exhibit. We may, however, remind our readers that the Sunbeam raidator lamp which is used by the Dowsing Radiant Heat Co. is one of the best upon the market.

Bruce Peebles. (Nos. 119, 140.)

There are comparatively few heavy-plant manufacturers in the Exhibition, and prominent among them may be mentioned Messrs. Bruce Peebles. The *piece de resistance* of their exhibit is their now famous motor converter. We have described this so many times in our pages that we do not need to give further details. We would, however, remind our readers that the opportunity of actually inspecting one of these interesting machines should be taken the fullest advantage of. The other features of the exhibit are mainly centred in types of alternating-current and direct-current motors made by Bruce Peebles at their Edinburgh works. There is a machine fitted with an automatic centrifugal starter which comes into action as a short-circuiting device when the motor has attained full speed. The contacts of the device are of ample surface ensuring good connection. The motor has a starting torque 70 per cent. of full load torque with full load current. A standard Peebles slip ring motor with removable cover for the slip rings is also shown. A feature of this machine, as also the one mentioned above, is the provision of adjustment screws in the end plates carrying the bearings. These screws are finely threaded and admit of the adjustment of the air gap for wear in the bearings. Peebles crane capstan mining and traction motors are also on view.

Sub-station Plant. Vickers, Ltd. (Nos. 80, 92.)

At one side of the Exhibition is the substation in which the Hammersmith supply is transformed and converted for use on the various stands. Berry and Westinghouse transformers are installed and Johnson & Phillips and Ferranti switchgear. The rotary plant is of interest and comprises a Vickers 300-kw. 50-cycle 6-phase rotary converter, direct-current voltage 220, alternating-current voltage 160, speed 750 revs. per min. It is of the Vickers standard type, fitted with interpoles to enable the machine to withstand heavy overloads. It is provided with a standard three-phase induction motor, direct-coupled for starting up the set on the alternating-current side. The rotary is provided with six slip-rings through which the six-phase current enters the armature. The rings are so constructed that by removing the bolts any ring can be replaced without dismantling the whole gear. The bearings are of the swivel type, the bush being of cast-iron lined with white metal. Lubrication is supplied by means of rings running in an oil bath.

Electric & Ordnance Accessories Co. (Nos. 80, 92.)

The display of E.A.O. specialities made by this company is one of the most striking in the centre of the hall. This exhibit is bridged by a large sign which effectively displays the name of the company and its principal products. Our readers are mainly familiar with these. We may mention in particular the wide range of Vickers' alternating-current and direct-current motors, centrifugal fans, propeller fans, ironclad switchgear and motor starters. The Vickers' controllers and lock-on and off switches should be inspected, and station engineers and contractors are specially directed to the "Eclipse" electric cooking and heating apparatus. The company's experience in this direction extends now over a period of years and as a result they have been able to develop a highly satisfactory and efficient apparatus. This portion of the exhibit will be in the hands of a lady demonstrator, who, as a qualified cook, will be able to bring out the advantages of the apparatus to the utmost. Vickers' arc lamps and metal lamps will be on view, also porcelain insulators, and Fireite, the latter being a new heat-resisting insulator. Timkin adjustable roller bearings and Vickers' Duralumin complete the exhibit.

OLYMPICS.

Was the King asked to open the Exhibition?

Will there be any wrecks at the foot of the Pope Lighthouse?

Why has Edison been put in the Gallery? He usually plays to it.

Is it true that there is a plot on foot to present Sir Joseph Lyons with a "Tricity" Cooker?

Where are the battery makers?

How many "new" metal lamps will the Exhibition give birth to?

Why Pintsch Aur lamp?

Under its reorganised scheme what firms will constitute the "allied" section in the new Manufacturers' Association?

B.E.A.M. (British Electrical Allied Manufacturers' Association Incorporated) May we hope that the scriptural significance of the "beam," and the "mote" will not be lost on the members of the reorganised Association?

Are the non-exhibitors now wishing they had?
Why did the Mazda-lier at the Venerable Bede?
Will the Lord Mayor really come to the Show?
Who said we should not have a band?
Have you been under the Bridge of Sighs in the Italian Garden?

THE NEW OSRAM LAMP.

The General Electric Co. seems to be able to startle the industry at times when it is least prepared for it. We have hardly recovered from the shock of the introduction of a 50-watt drawn wire tungsten lamp when we are asked to inspect a 20-watt 200-volt lamp with a jointless filament. As we announced exclusively in our columns last week, there is an Osram lamp of this size on view at the stand of the General Electric Co. By this it must not be implied that only one of these lamps is being shown, wrapped in cotton wool and placed in a glass case. On the contrary, they are there apparently in their hundreds, and visitors can take and handle them as they please. To give the fullest assurance that the filaments will stand vibration *when cold* as well as hot, two model tramcars have been fitted up and arranged to run down inclines towards each other and bumping against buffers in the centre. While these shocks are administered the lamps are switched on and off. The illustration on page 202 is a full-size view of the lamp, and its remarkably short bulb will be noticeable. Standard shades and reflectors, which are now largely used with carbon lamps, will, therefore, be available for use with the new 200-volt Osram. The station engineer may look askance at the new lamp, but he need not fear that it will do him any harm. It will encourage the smaller consumer to come on the mains, and extend the supply by that means, and it will encourage the uses of electricity for other purposes besides lighting, in any case.

THE INAUGURAL BANQUET.

On the evening preceding the opening of the Exhibition, Sir Wm. Preece, K.C.B., presided over an interesting gathering of Pressmen and members of the B.E.A.M.A. (incorporated). The proceedings were unduly prolonged by the large number of toasts and the absence of brevity on the part of one or two of the speakers. Sir Albert Rollitt proposed the toast of the evening, that of "The Electrical Exhibition," and was in rare good humorous form. He delighted the audience with, as Sir William himself acknowledged, "the best collection of stories he had heard for many a long day." Apart from his lighter passages, Sir Albert was rich in reminiscences of the early days of the electrical industry, and particularly of his association with Sir Wm. Preece, to whom he paid many tributes. In his reply, Sir William Preece reminded those present of his 60 years' work in the field of electricity, 30 years in connection with private enterprises and 30 years with the Post Office. At the beginning of next year Sir William said that he would celebrate his diamond jubilee as a civil engineer. He made the interesting statement that in the year 1834, when he was born, Elkington took out his first patent for the electro deposition of silver. He totally disagreed with the pessimists of the time, who believed in every country but their own. He had recently been to South Africa for his health, and was much impressed by the vigour and enterprise of the Britishers out there, in spite of the many Germans and Americans who were active competitors. He thought that the old country was well ahead in matters electrical and scientific. He announced, in speaking of the late Lord Kelvin, that Lady Kelvin would, at the next session of the Institution of Electrical Engineers, present that body with a bust of the great scientist. On that occasion and on the eve of a great popular Electrical Exhibition he should like to adapt certain lines from Shakespeare.

The note of the evening was, however, struck by Mr. H. Hirst in proposing "The Electric Supply Authorities." From the manufacturers' point of view, he put his finger on the pulse of the situation. He at first mildly chided the Exhibition authorities on their failure to make Olympia a blaze of light. If the matter had been apprehended in the right spirit the value of the Exhibition as a popular advertisement would have been enormously enhanced. He deplored the fact that the manufacturers had lacked necessary cohesion to provide this aggregation of illumination which would have made Olympia a centre of attraction over all London.

He also voiced the opinion that the Exhibition in great measure failed of its object because the various interests represented were scattered in all parts of the Exhibition. He hoped that when the next Exhibition was held, it might be in only a few years' time, they would see to it that the various sections of the industry were represented in a composite sense. He hoped to see the motor manufacturer, the lamp manufacturer, the arc lamp makers, the fitting designers and producers all assembled at their respective corners of the Exhibition. Then, from the public point of view, there would be no confusion in an inspection of the Exhibition. Each thing would be in its right place, and irrespective of the individual merits of the particular product, the public would be impressed with the advantages which they would derive by the uses of electricity for the particular purpose in view.

We discussed this matter after the dinner in an informal way and many people expressed the hope that something would be done with the suggestion at a future exhibition. But things don't hold well enough together to try it just yet!

ELECTRICAL
EXHIBITION.

HENLEY'S NEW WIRING SYSTEM.

Undoubtedly the chief attraction to electrical contractors and wiremen at the Exhibition is the new Henley Wiring System. We have already explained briefly the elements of this ingenious adaptation of metal sheathed insulated conductors to the requirements of inexpensive wiring. We were slightly in error in stating last week that the outer covering of the wire is lead. It is actually a special lead alloy which possesses, we understand, certain advantages over the pure metal. To turn now to the details of the system. The conductor is of copper, V.I.R. insulated, laid over with a thin copper tape, and finally covered with the lead alloy already referred to. The copper tape is utilised as the return conductor when the system is run concentric: where double wiring is needed the outer is just earthed suitably. A metallic continuity of tape is maintained throughout the running of the wiring, and this is accomplished by the use of an extremely simple fitting, if it can really be given this title. Fig. 1 will explain how the wiring is dealt with at either switch or ceiling points. An ordinary wood screw, which is turned home into a wood plug in the wall, is tapped to receive a long stud screwed through out its length. This stud provides a terminal for the copper tape on the special conductor, and also serves as support by which the wood block is firmly held in place. The illustration shows how the copper tape is clamped under a knob provided for the purpose. Now a piece of bare wire is taken from this to form one terminal (the earthed one) and how the insulated conductor is also passed through a hole in the block, for connection to the particular accessory that may be attached to it. This arrangement holds good for the concentric or earthed return application of the system. The twin conductors used are shown in Fig. 2, and Fig. 3 illustrates the special clamp and bonding device for use with these conductors.

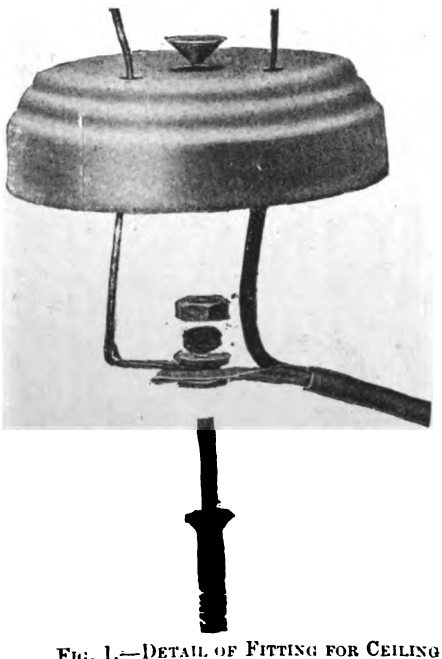

Fig. 1.—Detail of Fitting for Ceiling and Switch Points.

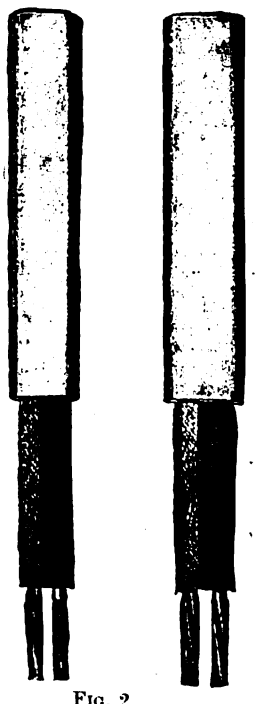

Fig. 2. Twin Conductors.

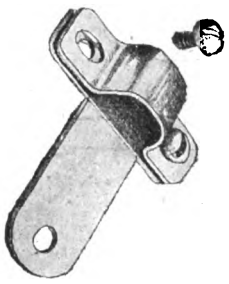

Fig. 3.—Bonding Clamp for Twin Wires.

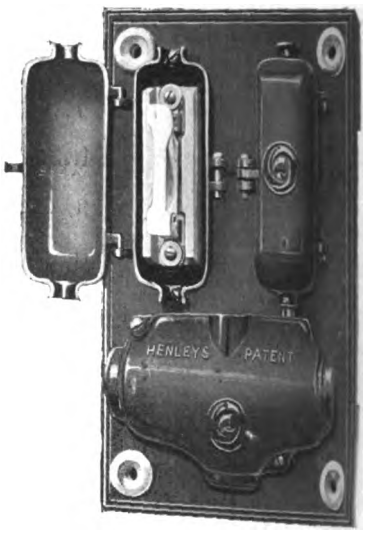

Fig. 4.—House Fuse Board.

The conductor is commendable because it is very flexible, can be run round bends and corners by mere bending with the fingers. Some difficulty is often experienced with these new wires in the matter of the bending. With Henley's new system this embargo is likely to be removed, because it is put on the market without a "bending tool," and this may be taken as a recommendation for easy working of the system. The copper tape after being turned back is doubled on itself for a space of about ½ in. to ¾ in., and a hole is punched through the two thicknesses of tape, and it is this which serves to hold the tape in position on the stud which acts as the earthing and bonding terminal. A special punch is provided for the making of this hole. The conductor is secured to the wall by brass saddles having one or two nails. The stand at the Exhibition is fitted out with specimen installations of the system, both double conductor and concentric. The work is neatness in the extreme, and the wiring is quite unobtrusive. There are samples of the conductor, which is made single and strand, on view, and visitors can see for themselves how the conductors can be worked. Messrs. Henley's have introduced this interesting system to provide the industry with an inexpensive method of surface wiring, particularly for houses of moderate rental. They claim it to be a complete solution of the cheap wiring ploblem. The system is, of course, completed by a suitable distribution box having S.P. fuses, and a common terminal bar to receive the ends of the copper tape. We understand that the company has laid down a quantity of special plant for the making of the new conductor, and that a large number of orders have been received for it. Fig. 4 shows the house fuse board and dividing box which Henley's recommend for use with the above system.

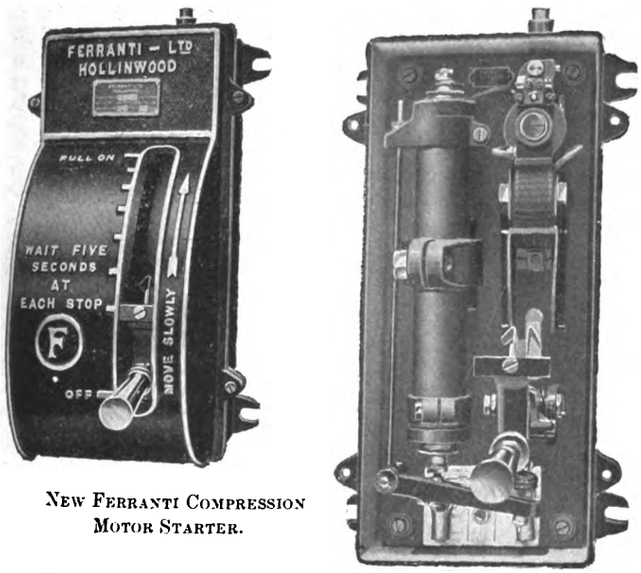
OLYMPIA EXHIBITION.—*Continued.*

Ferranti, Limited. (Nos. 102, 113.)

We have already complimented Messrs. Ferranti, Limited, upon the design and arrangement of their stand. Now that the exhibition is open it appears in bold relief in the body of the hall among the neighbouring exhibits. It is a model of how electrical control gear and apparatus should be displayed in an exhibition of this character. We have found that our good opinion has been generally endorsed since the opening of the show, and the officials of the company will, we are sure, feel particularly proud of the distinctive nature of their exhibit.

To central station engineers and electrical contractors the chief object of interest on the Ferranti exhibit is the new compression motor starter. As we stated in our last issue, this is an entirely new application of the carbon rheostat to the function of motor starting. In fact, the starter is a combination of a compression rheostat with a circuit breaker. The successful development of the design has hung



New Ferranti Compression Motor Starter.

upon the provision of an insulating lining to a steel tube which would be fireproof and have the same coefficient of expansion as the steel. We understand that this desirable result has been obtained, and the company is now in a position to supply a form of starter in which contacts, connections, studs, plates, wires, grids and woven resistances have absolutely no place. We illustrate the simplest form of starter in which the resistance element is contained within a single steel tube lined with the insulating material to which we have referred. Within the tube is a great number of extremely thin carbon discs. These discs form a column in the tube, with a fixed terminal at one end and a movable one at the other. This movable terminal is so arranged that by the movement of the circuit-breaker handle the lever comes into operation, actuates the movable terminal and exerts pressure on the column of discs. This pressure is, however, not applied until the shunt circuit of the motor has been closed by the first movement of the circuit-breaker handle. Further movement of the handle brings about the pressure on the column of discs, the resistance in the motor circuit is gradually reduced, and by the time that it is entirely cut out the circuit-breaker is closed. The handle of the breaker is passed through a slot in the iron cover which completely encloses the apparatus. The edge of this slot is marked with instructions that the handle be held for 5 seconds at each of the lines on the slot. This ensures even starting. There is a no-volt and overload release to the breaker, so that the motor is absolutely protected. A mechanical trip to the breaker latch is provided for the opening of the switch and the shutting down of the motor. The starter occupies a minimum of space, and can be placed complete on a wall surface or fastened directly to the motor carcase. The starter is at present manufactured in sizes up to 30 H.P., and it can be combined with shunt regulator and separate circuit-breaker in a complete motor control ironclad panel. By the increase in the number of rheostat tubes the larger sizes of motors can be controlled. The same principle is introduced into the Ferranti regulators which are offered in various sizes for controlling the speed of small motors. In this class of apparatus carbon washers resting on quartz tubes are made use of, and pressure is brought to bear upon them by a common face-plate, which is acted upon by a central hand-wheel. We would strongly recommend to engineers who are interested in the control of motor circuits to take an opportunity of inspecting this interesting portion of the exhibit.

Mirrlees, Bickerton & Day. (No. 8.)

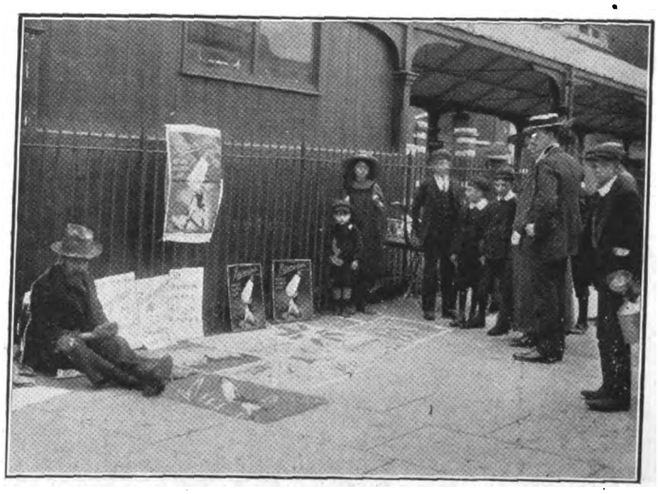
This exhibit includes a "Mirrlees-Diesel" oil engine of the four-cylinder type, 160 B.H.P. and is a duplicate of a considerable number of engines the company have made for driving dynamos on board warships, most of the recent British battleships and first-class cruisers being fitted with these engines. The engine is of the completely enclosed type, with forced lubrication to all bearings, and is direct connected to a dynamo, built by the Lancash,re Dynamo & Motor Co. Four separate oil supply tanks containing different grades of oil are connected with the engine in such a manner that the engine can be switched over from one grade of oil to another whilst running, the object being to demonstrate that no alterations are necessary to enable the engine to work with widely varying qualities of oil. The dynamo is connected with a water resistance, and suitable switches are provided so that full-load or partial loads can be switched on and off as desired. Visitors will have an opportunity of noting the behaviour of the engine on widely varying loads. The engine is exceedingly compact, and occupies little space and forms a most interesting exhibit.

Pooley & Austin. (Nos. 49, 74.)

The exhibit of this company is comprised of the manufactures of three of the firms for which it holds sole agencies. These are Messrs. Mawdsleys (Ltd.), Spagnoletti (Ltd.) and Engineering Instruments (Ltd.). The Mawdsley display is confined to direct-current dynamos and motors ranging in size to 300 H.P. A Mawdsley 50 kw. dynamo is also shown direct-coupled to a four-cylinder vertical oil engine. The products of Messrs. Engineering Instruments and Spagnoletti are in the nature of switchgear and switching apparatus, and representative types of these have been selected and displayed.

An Advertising Tramp.

A touch of humour was given to the opening of the Electrical Exhibition at Olympia on Saturday last by a unique advertising scheme of the Brimsdown Lamp Works. A well known Fleet-street artist, dressed for the part in a scraggy sandy beard, tow wig, battered hat, battered coat and vest and cast-off "bobby's" trousers, alighted from a taxi in a quiet side street near Addison-road. Adopting the footsore walk of the type he represented he crawled along to the main entrance of Olympia, passing on the way several acquaintances. Assuming a "husky beery" voice he asked permission of a six-foot-six commissionaire to make sketches near the gateway. Permission having been graciously granted to the "old bird," he commenced to clear the paving stones, but did not disclose his advertising scheme until six sketches were completed. Then placing two showcards and a large poster in the background, he wrote advertising phrases on each sketch, much to the amusement of the onlookers. The tramp artist had the unique experience of having coppers flung to him in



The Brimsdown Pavement Artist at Olympia.

charity by electrical men whom he knows intimately in his business capacity of advertising specialist. During the occupation of the pitch, from 3:30 to 5:30, the "takings" amounted to 7s. 7d.—85 pennies, and a sixpence given by a charitable elderly lady on her way to Addison-road Station. Mr. J. Conway Price, the "gentleman" in question, pays a glowing tribute to the kindness and sympathy he received from the policeman and commissionaire at Olympia, who frequently gave him a few words of encouragement. In return for the coppers he received Mr. Price handed out "Brimsdown" Turkish or Virginian cigarettes.

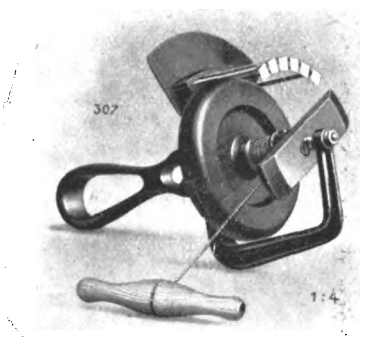
Union Electric Co. (Nos. 101, 114.)

The exhibit of the Union Electric Co. is noticeable from practically all parts of the exhibition. It is one of the most striking of the "open" stands in the show. The centre of the exhibit is occupied by what appears to be an ironclad switch pillar of large dimensions. As a matter of fact, it is the office of the exhibit lined up with the sheet metal work used by the company in many of their h.t. switchgear designs.

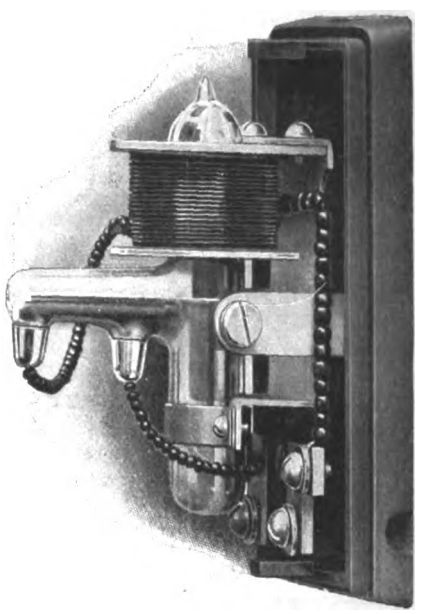
The products of the Union Company are so varied that it is difficult to single out for special notice any one of them. The requirements of many branches of the electrical industry are met by the company's manufactures, and we may specially itemise arc lamps and accessories, including the famous "Excello," "U.E.C." motors and dynamos in all types and sizes, Hartmann & Braun instruments and ironclad switchgear and motor starters. Turning to the last mentioned first, we may specially comment upon the "Fortiter" automatic field regulator. This is one of the simplest of the solenoid type of regulator, which has come under our notice. The solenoid is provided with a movable core to which is attached a trough of insulating material filled with mercury, and the ends of the resistances are fixed above this trough in the form of a comb having teeth of gradually decreasing length. It is obvious that by moving the comb vertically a greater or smaller number of the resistance coils



PORTABLE LABORATORY FREQUENCY INDICATOR.

are put in and out of circuit. This apparatus should be inspected, as it is shown in operation. The switchgear section of the exhibit is arranged, as we have already intimated, on somewhat striking lines. Included in it are two oil-break switches designed for pressures as high as 20,000 volts. There are also two switches shown for 10,000-volt circuits, and these can be arranged for lever or solenoid operation. An interesting feature of these switches is a special hollow insulator, in which the copper conductor passes through a non-hygroscopic insulating tube to the cast-iron flanges at each end of the insulator, and is surrouned by a fluted hollow porcelain insulator, which tapers in both directions from the centre. We are informed that this special pattern of insulator normally rated for 10,000 volts will stand a breakdown pressure as high as 47,000 volts. The Union switchgear is well known in this country, and has been installed in most of the great centres of industry, where a power supply either for public or private sources is available. Another feature of the h.t. exhibit is a form of water resistance for use with lightning arresters of a.c. circuits. We may also mention an inductionless resistance in which a special material known as "Ohmit" is introduced.

Instruments.—In the instruments shown, in addition to the usual patterns of ammeters and voltmeters, there is an interesting selection of frequency meters of the vibrating reed type. These are made on the Union Hartmann-Kempf system. A synchroscope of the vibrating reed pattern is included in this series. The hot-wire instruments are of interest, because of the use of a special platino-iridium alloy which makes the instruments independent of the temperature of the surrounding air. In this same series is a new line of ammeters for use in wireless telegraph installations, which are made to carry currents up to 100 ammeters. The instruments are of the straight-through type—that is, they have no external shunts—the platinum-iridium strips carrying the current being arranged symmetrically in cylindrical form. We understand that a wattmeter of



UNION CURRENT LIMIT SWITCH.

the same pattern is also shown for wireless telegraphy. The instrument section is so full of items of interest that it would take almost the whole of our exhibition space to describe the instruments in detail. We may, however, enumerate some of the other patterns shown. There is a line of electro-dynamometric wattmeters of the moving-coil type, a range of moving-coil instruments, a power-factor indicator of the differential moving-coil pattern for one and polyphase circuits, portable ammeters and wattmeters for incandescent lamp testing, small precision instruments, a new form of current limiter and an earth indicator.

Dynamos and Motors.—One of the most interesting of the types of motors shown is a three-phase loom motor having a cradle suspension. This is made in sizes from ½ to 1½ H.P., and is said to have high efficiency, a high power factor and a large starting torque. The new "U.E.C." motors and dynamos exhibited are of either the open or enclosed patterns, and there is being shown a totally enclosed 6 H.P. machine having a special cooling arrangement, whereby the air is constantly circulated through the motor, and is passed through a cooling grid. In this same section is exhibited a petrol-electric set for country house lighting or cinematograph work.

Arc Lamps.—The arc-lamp exhibit is one which will doubtless attract a considerable amount of attention. It includes the "Union" searchlight projector, which surmounts the pedestal in the centre of the stand, and a variety of enclosed and "Excello" lamps which are appropriately grouped on the stand. Bioscope photographic arc lamps and inverted arc lamps are also displayed.

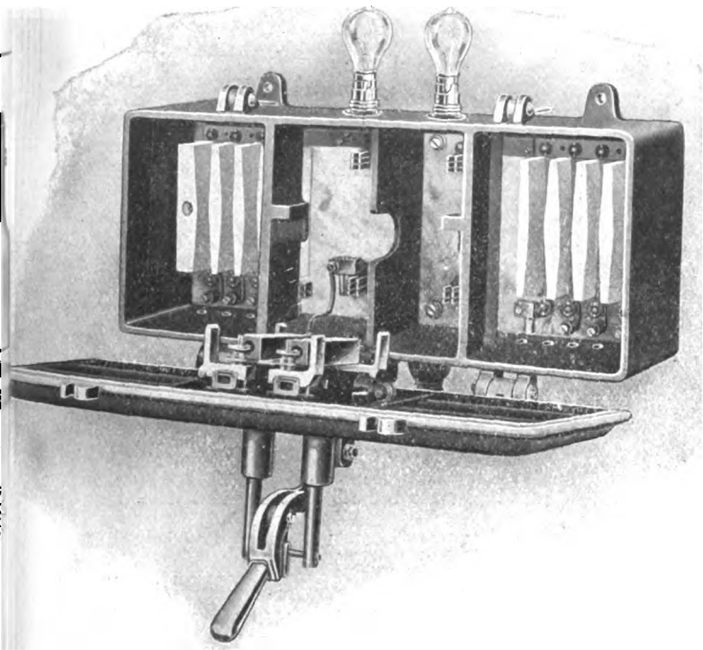
OLYMPIA EXHIBITION.—*Continued.*

Electric & Ordnance Accessories Co. (Nos. 80, 92.)

This exhibit is among the few in the exhibition which are completely open from all sides. The stand is a large one near the centre of the hall, and is surmounted by the bridge sign which bears the name of the company and its principal manufactures. Of particular interest is the complete range of Vickers direct-current motors, which are shown in sizes from 18 H.P. to 50 H.P. These machines have stood the test of hard service in all parts of the country and Colonies, and they certainly have a most businesslike appearance. The yoke and poles are of cast steel, the poles being fitted with laminated tips. The armature coils are former wound dropped into open slots, which are closed by specially treated wooden wedges. There is a generous provision made for cooling the field and armature coils. Where motors are required to be reversed or are subject to severe overloads, they are fitted with interpoles. Our readers should take special note of the brush-holders and terminals of these motors. The brushes are of the box type, and can be adjusted by the simple movement of a milled disc. The terminals are conveniently placed on the motor shell for wiring purposes. The Vickers alternating-current motors exhibited also display numerous points of interest. Electric power contractors and industrial power engineers will find the display of motors, starters, ironclad switchgear and controllers one of the most comprehensive in the exhibition. The Electric & Ordnance Accessories Co. have specialised for some years past in controllers of all kinds, and they are able to offer a variety of designs for almost every purpose. Vickers controllers are made for cranes, machine tools, lifts, hoists, printing presses and similar classes of power service. We understand that the company is prepared to supply controllers for any standard or special apparatus. Metal and mica construction is a feature of the apparatus, and the spark guards are fitted with the company's new insulating material known as "Fireite." Efficient magnetic blowouts are included in this important equipment. A switch recently patented by the E.O.A. is that known as the lock-on and off switch. In this a quick break and make is obtained and the blade is locked both in the on and off positions by means of steel balls.



E.O.A. Crane Switch and Panel.

The insulating material to which we have just referred is a special heat-resisting substance which the company is manufacturing at Hanley. It is recommended for carbon guides, arc lamp caps, burner nozzles and, in fact, anything which is brought into direct contact with a flame. It has considerable strength, possesses a good even surface and is, we understand, cheaper than any other similar material at present on the market. It is possible to supply it in almost any shade required. Vickers Duralumin, which is a substance to which we have previously referred, is also on view on the stand, and is shown in a variety of specimens. It is unaffected by mercury, is non-magnetic, will not oxidise, and will withstand the action of sea or fresh water. It will take a polish equal to nickel plating. It has a tensile strength of 40 tons per square inch, with very little elongation, of 28 to 30 tons per square inch with 18 per cent. elongation in 2 in., or 25 tons per square inch with about 20 per cent. elongation in 2 in. It can be supplied in 15 different grades and qualities, and in the shape of plates, sheets, screws, rivets, bars, wire, forgings, stampings, angles, tees, tubes and rolled or extruded sections. The material is not suitable for castings. The Timken roller bearing is a friction-defying device which is capable of taking loads from 270 lb. to 1,935 lb. It is of paper construction, and so arranged that end thrust can be supported as well as ordinary radial load. This arrangement also admits of the adjustment of the bearing to compensate for wear.

In every way the company must be complimented upon the manner in which its exhibit has been displayed.

The Lancashire Dynamo & Motor Co. (Nos. 122, 137.)

As explained in our last issue, a most important exhibit on this stand is a 4 ft. by 4 ft. by 10 ft. Buckton planer fitted with the "Lancashire" patent reversing motor drive. This drive has been so successful that upwards of 150 equipments have been supplied during the last 18 months. The planer will take two $\frac{5}{16}$ in. by $\frac{1}{16}$ in. cuts in mild steel at 75 ft. per minute. The cutting speed may be set at will to any speed between 25 ft. per minute and 75 ft. per minute by turning one handle, and in a similar manner the return speed may be varied between 120 ft. per minute and 220 ft. per minute.

Special attention is called to the accelerating device, which is in the form of a small switch worked by adjustable stops on the planer table. It performs two functions: (1) Speeding up between cuts when two or more surfaces some distance apart are being planed. (2) Speeding up when the tool has entered the work, so that higher cutting speeds can be used without extra wear on the cutting edge of the tool. If necessary the table can be retarded before the tool leaves the work, so that the end of the work is not broken. This has never before been done by any system of planer driving.

The switchgear used is simply that for an ordinary variable-speed motor, and is made in ordinary starting-panel form. The only switch moving at each reversal of the planer is the reversing switch, which only deals with the field current of the generator, this being equivalent to the current required by a few lamps.

The "Lancashire" system of driving a planer or other tool by a reversing motor is as follows: A motor-generator is mounted on the upright or in any convenient position, and the motor is connected to the power curcuit. Either alternating or direct current may be used, and if no current is available the generator may be driven from a line shaft.

The generator is connected electrically to the planer motor which is direct coupled or geared to the planer driving shaft. This generator and motor are direct-current machines, and may be wound for any convenient voltage. A reversing switch is actuated by one light tappet rod from the reversing gear of the planer. When this is thrown over it reverses the direction of the current in the field winding of the generator, thus reversing the direction of rotation of the planer motor. At the same time it so regulates the voltage of the generator as to cause the planer motor to run at the speed required according to whether it is on the cutting or return stroke.

The tappet rod mentioned above is the only mechanical connection between the switchgear and the planer. The cutting speed may be varied by hand to suit the work being done by means of a regulating resistance in the generator field. This gives a constant return speed, but if desired the return speed can be varied also.

Write for New List No. . . 177.

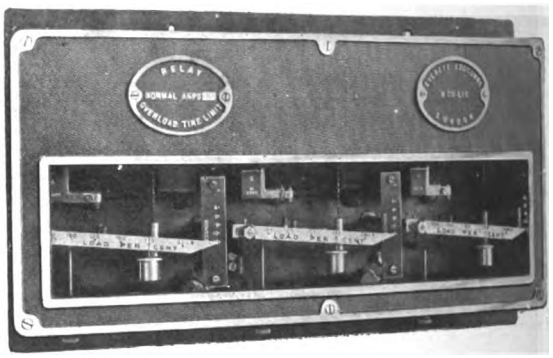
The planer table is driven by a machine cut spiral pinion-gearing into a machine-cut rack on the underside of the table. On the outer end of this spiral pinion shaft is a spur-wheel driven by a similar steel spiral pinion coupled up to the shaft of the reversing motor of the Lancashire Dynamo Co.'s "Lancashire" drive. With this spiral gear there are always a number of teeth, usually not less than four, in mesh simultaneously with the rack, and the motion of the table is effected noiselessly with extreme smoothness and without any jar or chatter, while the frictional resistance is reduced to a minimum. A distinguishing feature, and one which tends to greatly increase the output of the machine is the patent power feed and traverse motion. By means of this the feed of any tool box in any of its automatic motions can be varied over the whole range from a fine feed to a broad finishing cut with suitable intermediate rates.

The feed on all the motions can be stopped, reversed or varied instantly without stopping the machine. The cross slide can be rapidly traversed up and down by power, and all or any of the tool boxes can be rapidly traversed by power in any of their automatic motions. All these various motions are actuated by the patent power drive, and all the regulating handles are conveniently arranged to be operated from one side of the machine, and from approximately one position.

Everett, Edgcumbe. (No. 66,)

(*The Luxometer.*—In our last issue we gave a short description of this interesting instrument, but inadvertently omitted to mention that it was manufactured by Messrs. Everett, Edgcumbe. We take this opportunity of correcting this omission.)

This well-known instrument firm has an effective display of the large variety of instruments which it has been regularly manufacturing for many years past. We think that central-station engineers will be particularly interested in the alternating-current relays on view. We illustrate one of the induction overload pattern with inverse time element, a feature of which is that both the current and time settings are adjustable over a wide range. Further, the time limits can be relied upon to keep their proportional settings at all overloads, however heavy, consequently accurate discrimination is obtained. We also show a pattern of reverse relay, in which although a pressure winding is provided, it simply determines the direction of the flow of the current and not the magnitude of the overload required to trip the breaker which it controls. The makers contend, and apparently with reason, that a reverse power relay is not what is required and that a reverse relay should act or not according to the magnitude of the current flowing. Owing to the fact that on the occurrence of a bad short the pressure may fall very seriously, it is essential with a reverse power relay to make it extremely sensitive, and set it excessively fine. For example, if such a relay is required to trip at full-load current when the pressure falls to 10 per cent. of its normal value (a by no means unlikely occurrence) it must be set to trip with less than 10 per cent. of the full-load current at normal current. As a result, such a relay will almost certainly come out unexpectedly and when least wanted. With Messrs. Everett, Edgcumbe & Co.'s reverse relays, on the other hand, such an instrument can be set for 50 per cent. of the full load current and satisfactory working will be ensured owing to its independence of the pressure.



EVERETT EDGCUMBE THREE-PHASE INDUCTION RELAY.

Amongst the interesting exhibits we may mention the company's Graphic instruments, which are made for all circuits and voltages, their rotary synchronisers, an electrically-operated engine-room telegraph and a variety of tachometers and tachographs. The leakage indicators shown should also attract attention, particularly as they have been in use for some years, and the makers can vouch for their reliability. There is a line of water-tight instruments shown, which should be seen by electric power contractors who require to instal this pattern of instrument in damp and difficult situations in factories and workshops. The photometer equipments displayed by Everett, Edgcumbe are of the utmost interest, and our readers will find the attendants at the stand willing to supply any information and also to demonstrate the operation of the instruments. The importance of good illumination at the present time is being constantly emphasised, and on this account the attention paid by this firm to reliable instruments for its measurement should not go unrecognised.

Johnson & Phillips. (Nos. 123, 136.)

Arc Lamps.—A prominent feature of this exhibit is the "Metroflam" flame arc lamp. This is a magazine lamp, in which a number of carbons are employed, but in spite of this fact the change from one pair to the other is accomplished without any interruption of the light or objectionable flickering. We shall return to this interesting lamp in another issue, and at the moment may refer to the display of the company's other products.

Cables.—A particularly fine show is being made of v.i.r. and paper-insulated cables. Samples of these have been carefully grouped in show cases, and by an inspection of the cross-sections of the cables it is possible to observe the efficient manner in which the insulation and other protective coverings are applied. The cable manufactures are supplemented by examples of "J. & P." service and straight through boxes. The latter has been designed for colliery use, and admits of the connections being made without the use of solder. Mica and porcelain are the only insulating materials introduced.

Machinery.—A 10 kw. motor-generator designed to operate at 1,000 revs. per min. is exhibited. The output of the generator is 100 amperes at 100 volts. Ball-bearings have been introduced into this machine, and we understand that these bearings are so designed that they will not require attention for 12 months. The system of lubrication employed also guards against leakage.

Switchgear.—The switchgear portion of the exhibit occupies the

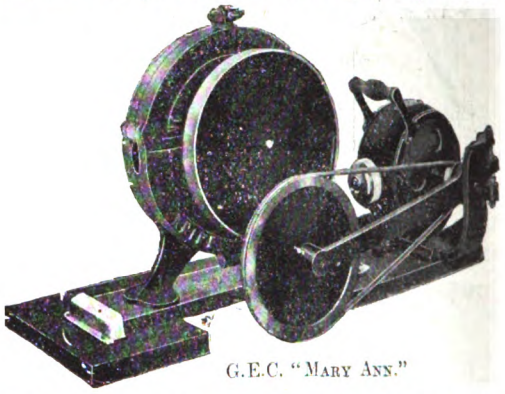
bulk of the floor space available. There is a remote control 10,000-volt three-phase panel built up in a glazed brick cubicle. The cells are arranged to separately accommodate the 'bus bars isolating switches, current and potential transformers and oil-break switches. The operating front is of marble, and contains the necessary instruments and gear. The oil switch is lever operated, and is provided with a strip coil and free-handled attachment, three single-phase relays come into operation on overload and also reverse, and bring the strip coil into circuit for the operation of the switch. The instruments on the board are of the Johnson & Phillips well-known hot-wire type. An interesting lamp-indicating device is fitted in connection with the oil switches to show whether the switch is in the on or off position. In another part of the switch exhibit will be noticed a 3,000-volt board designed to comply with the latest Home Office regualtions. A complete enclosure is made round all the live parts by means of extensions in every direction with the minimum of trouble. There is also a low-tension board on which one of the panels is fitted for the control of a standard tramway feeder of 600-amperes capacity. The other panel is connected in circuit with the apparatus on the stand-by way of the motor-generator already mentioned. The panel controls two separate circuits of 220 volts, one single-phase alternating-current and the other direct-current, and a further circuit of 80-volts direct current. The sub-station at the right-hand side of the Exhibition near stand 241 is also equipped with a "J. & P." 2,000-volt two-phase board, being part of the supply from the Hammersmith Borough Council. This board is fitted with two-phase oil switches with overload direct operating drop coils. There is also in the sub-station a "J & P." low-tension board. Tramway and power transmission engineers will be interested in the "J. & P." limiting resistances, which provide protection from the effects of lightning where horn arresters are used. The resistances comprise three earthenware troughs filled with graphite powder, having a known ohmic resistance, and these are coupled in series with the horn arresters, so that in the event of the latter arcing over only a certain amount of current can flow to earth. The powder is of such a consistency that it returns to its original condition after the passage of a severe current, so that it automatically sets itself in readiness for the next discharge.

General Electric Co. (Nos. 103, 112, 125, 134.)

This exhibit is practically in the centre of the hall, and is divided into two parts, one at stands 103 and 112, on the left-hand side of the

200 v., 16 c.p., Osram Lamp.

main hall, and the other at stands 125 and 134 on the right-hand side. The first mentioned is the larger of the two, and is devoted to the illumination products and fittings of the company. It includes a prominent display of Osram lamps, and particularly the new 200-volt 16 c.p. 20-watt size, to which we refer elsewhere. The stand is surmounted by a large sign, which is a bas-relief reproduction of the company's new poster, representing as it does a pair of hands holding up an Osram lamp. In this particular case the lamp is lighted, and produces a very fine effect. The display of lanterns and fittings is brilliant in the extreme. The company appears to have spared no effort to show how its designs can meet the requirements of electrical illumination at the present time. The display ranges from the most

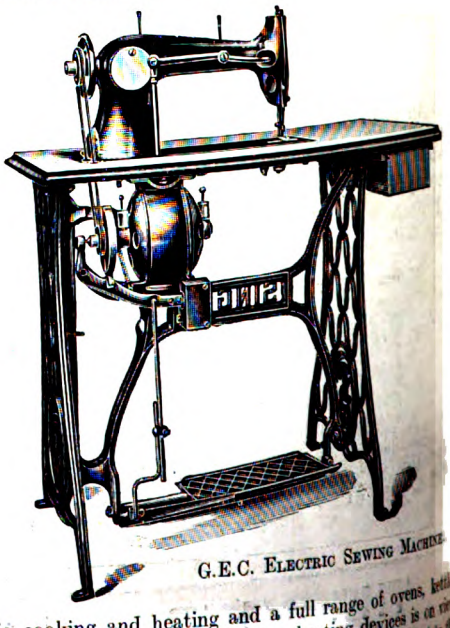


G.E.C. "Mary Ann."

elaborate and expensive chased fittings to the neat and artistic pendant which the moderate man will install in his house or flat. The range of shop-lighting fittings is such as would delight the eye of the proprietor of the largest emporium or the smallest tradesman. The display of the Butt magazine flame lamp and a variety of other arc lamps and accessories has been prominently and tastefully grouped.

G.E.C. Convertible Set.

Stands 125 and 134 contain the heavier portion of the company's products, such as "Salford" ironclad switchgear, "Witton" motor starters and motors, country-house lighting plants, "Witton-Kramer" drilling machines, &c. A portion of the same stand is set apart for an interesting display of certain processes in the manufacture of the Robertson lamp. The exhibit includes the Archer system



G.E.C. Electric Sewing Machine.

of electric cooking and heating and a full range of ovens, kettles, irons, radiators and a number of other heating devices is on view. In fact, the company's exhibit contains so much of interest to the

INTERIOR OF MODEL 216. POLYPHASE WATTMETER.

All these New Instruments as well as our A.C. Switchboard Voltmeters and Ammeters, Models 151 and 156, are fully illustrated and described in our New Catalogue 16. This whole group of Instruments embodies the results of several years exhaustive study and scientific investigation of all the complex electrical and mechanical problems involved in the development of durable, reliable, sensitive and accurate instruments for use on A.C. circuits. These Instruments are far superior to any that have ever been produced for A.C. Switchboard service, and the above illustration will indicate the exceptional character of the interior work.

By means of this new group of Instruments an A.C. plant may be more efficiently controlled than has hitherto been possible, thereby producing greater economy in operation and maintenance.

We invite the most critical examination of every detail of each member of the group.

public that a full inspection of everything that it has to show would practically cover all the branches of electrical manufacture at the present time.

The Siemens "Tantalum" Showcard Competition. (Nos. 179, 184.)

We are informed that approximately 2,000 designs were submitted for this competition, and that each has had careful consideration by the staff responsible for the selection of the winning designs. A first prize of £75 was offered, with a second prize of £25, together with a prize of £5 for any designs of more than average merit which the firm decided to adopt and reproduce. The task proved somewhat difficult, and eventually it was decided that the two best designs should be bracketed as of equal merit, and the £100 prize divided between the two successful competitors. Therefore a prize of £50 goes to Mr. L. Sutton Wood, 3, Featherstone Buildings, Holborn, W.C., and a similar prize of £50 to Mr. Frank M. Barton, 2, Montague-road, West Ealing, W. We shall reproduce a black-and-white drawing of Mr. Barton's design, which will be attractively printed in several colours, and we illustrate Mr. L. Sutton Wood's design in this issue. Further accepted designs were submitted by Mr. R. F. Higgins, 8, Grenville-place, Maida Vale, W., and Mr. F. Insall, Waterlane, Brislington, Bristol, who are recipients of prizes of £5. The designs of non-successful competitors will be returned in due course, and it is hoped that they will arrive in good condition.

ONE OF THE "TANTALUM" PRIZE SHOWCARDS.

A Remarkable Fuse Wire.

At the stands of Parmiter, Hope & Sugden and Simplex Conduits (Ltd.) demonstrations are being given of the latest in fuse wire and fuses. Mr. Vernon Hope, who is well-known as a maker of switchgear, has been experimenting for the past three years with fuses, and as a result of his labours has been able to present the industry with a satisfactory solution of the problem of the fuse. We understand that in this undertaking he has received material assistance from Simplex Conduits (Ltd.), who have one of the few fuse wire making plants installed at their Birmingham works. Hope's "Bi-metal" fuse wire is remarkable in that it actually possesses a definite time element, a function it was at one time thought impossible to obtain with a fuse wire. The wire, as its name implies, is made up of two metals—copper, in the shape of wire and placed as a central core, and a special low-melting alloy which concentrically surrounds the copper wire. The wire will carry 90 per cent. of its fusing current without heating, and may be touched by the fingers when within 10 per cent. of its blowing current. It will carry five times its fusing current for short periods, and is not liable to oxidation. The advantages of this material will be at once obvious. A porcelain fuse handle or cartridge fuse will not get hot when working up to the limits of its capacity, as is always the case with copper or lead-tin fuses. The fuse does not splutter on blowing, and the low-melting metal is not volatilised except on dead short circuits. On the stands of the exhibitors above mentioned special boards have been erected to allow of demonstrations of the bi-metal fuse wire to be made and comparative tests with other makes of wire carried out.

We were present at some tests and were struck with the low watts loss. On a 70-ampere copper fuse the loss was 45 watts and on bi-metal only 7 watts. A 20-ampere fuse was also shown to be able to carry 80 amperes for a few seconds without blowing. The 12-ampere arc lamps on the stand are run on a 15-ampere bi-metal fuse.

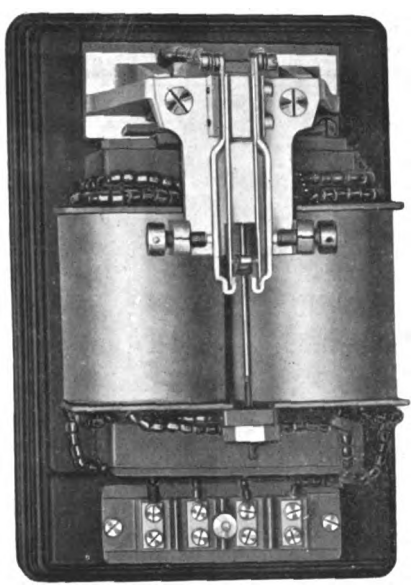
PATENT
VIBRATORY CONVERTER.
D.C. to A.C.

PATENT
VIBRATORY RECTIFIER.
A.C. to D.C.

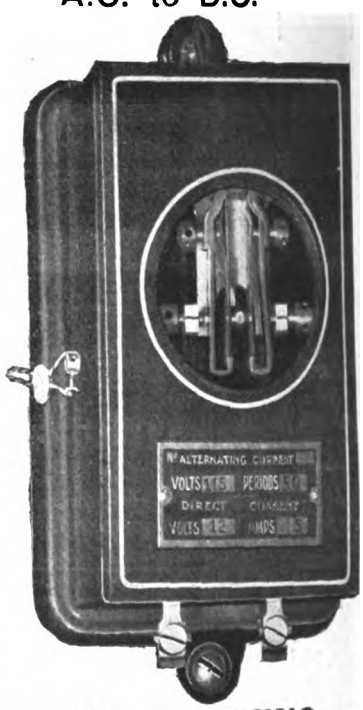
LOW PRICED, RELIABLE AND EFFICIENT.



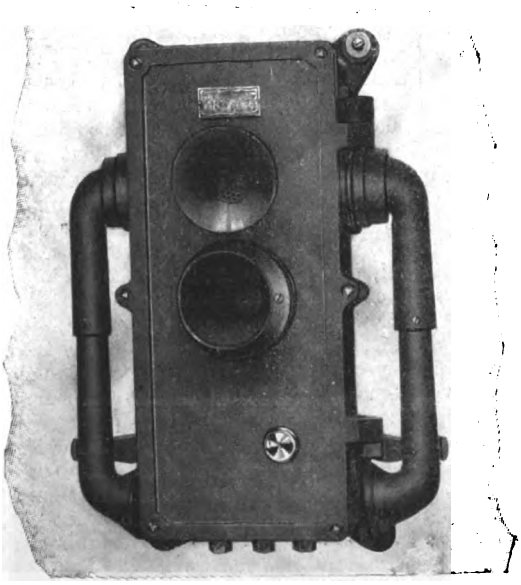
VIBRATORY CONVERTER.
A substitute for pole changers, magneto or rotary converters in telephone exchanges and installations. Will convert a source of direct current into true alternating current of any desired voltage and frequency. Efficiency 85%.

VIBRATORY RECTIFIER
for charging of accumulators and working of direct current apparatus from alternating current circuits. Can be adjusted to work on A.C. circuits of any frequency between 45 and 60 periods.

Efficiency up to 90%.



BOTH INSTRUMENTS WORK WITHOUT ANY SPARKING.



Patent LOUD SPEAKING "TUNNEL" TELEPHONE.

For Railways, Ships, Mines, etc.

In gas and watertight well lacquered cast-iron case, comprising high frequency vibratory converter, loud calling hooter, 2 loud speaking receivers fitted inside the case and connected to 2 hearing tubes, automatic switch hook, calling push, induction coil and loud speaking transmitter with interchangeable capsule microphone.

All sensitive and working parts are entirely enclosed in the telephone case. The vibratory converter enables calling to be made over any distance from a battery of 2 dry cells.

Pope's Electric Lamp Co.

It was a decidedly novel idea which this company decided upon for its stand at Olympia. The central feature of the exhibit is a tall lighthouse, the lantern of which reaches up to the gallery roof. The interior of the lantern is illuminated with a number of Pope lamps, and radiating to the four corners of the stand from the lantern are four signs made up to represent beams of light from the lighthouse. These signs bear in letters of light the name "Pope Lamps." The adjoining illustration gives a good idea of the effective manner in which this has been carried out. The exhibit is a centre of attraction, and reflects great credit upon the company. It is difficult to display a commodity of this character in the most effective manner, but the company has undoubtedly succeeded on the present occasion. The surrounding parts of the stand are devoted to individual exhibits of the different classes of lamps made at the company's works at Willesden, London. The metal lamps have a high efficiency, and are made up of squirted filaments. A demonstration of the durabiliy of the filament is in constant process of showing, there being a motor-operated mechanism which raises each of four lamps in turn to a certain height, and then allows the lamp to drop with a jerk to the full length of a flexible cord. This administers a sharp shock, which is a severe test of the strength of the filament.

Pope Lighthouse at Olympia.

Benjamin Electric (Ltd.).

The development of the metal lamp cluster has necessitated the introduction of special fittings which can be used for the convenient spacing of the holders for combinations of metal lamps. The wireless clusters exhibited by the Benjamin Electric (Ltd.) are typical of the neat designs which are possible in this direction. It was at one time an extremely difficult matter to wire up a cluster fitting, because the space at disposal is so small. With the Benjamin wireless cluster this difficulty is obviated. The lamp-holders are mechanically connected to the bodies, and no wiring of any kind is necessary, except that of coupling each cluster to its circuit. Electrical contractors should make a special point of visiting this stand (151) and inspecting these interesting cluster bodies. A feature is also being made in the exhibit of watertight holders and combination holders for use with special reflector fittings. These are most useful for shop window lighting, where it is necessary to make up the holder as part and parcel of the shop fittings. We illustrate typical examples of these fittings. The Benjamin patent friction drive screwdriver should also be examined, as the makers claim that it is superior to the ratchet screwdriver. It can be inspected at the exhibit and tried on screws of various sizes.

DEVELOPMENTS IN LAMPS AND ILLUMINATION.

The Olympia Electrical Exhibition is in every sense of the term a striking example of what can be done with modern electrical illuminating units. In the present issue we have attempted to concentrate attention on the most recent improvements in arc and metal lamps and their application to most purposes of illumination.

Since we published our last special Flame Arc Lamp Issue a great deal has been done in the development of new patterns and in the persistent application of existing types to the requirements of all classes of light users. It is pleasing to be able to record distinct progress in all branches of electrical illumination and those of our readers who are able to take advantage of the Olympia Exhibition will confirm the opinion that every effort has been made to place electrical illumination on a thoroughly practical and commercial basis.

There can be no doubt that the authorities of the Exhibition have lost a great opportunity in regard to the lighting of the exterior of Olympia. The signs erected on the front of the building are not quite suitable to convey to the public at a distance that an important show of the latest electric-lighting appliances is being made. Mr. Hirst, at the inaugural banquet, expressed the opinion that Olympia should have been "a sea of light." With so many manufacturers of lamps taking an interest in the Exhibition it should have been a simple matter to get together a co-operative scheme for the external illumination of Olympia. On the score of cost we feel that the project could have been carried through with a minimum of expense. The illumination material employed in London at the Coronation for the outlining of buildings might have been purchased after the festivities and applied to the outlining of Olympia with light for the opening of the Exhibition. There is no record of this huge building having ever been illuminated in this way. This fact alone would have drawn thousands to the Exhibition and would, we are sure, have been the wonder of London. Still, the opportunity is one which will present itself again and no doubt it will be put to its fullest use. We cannot, of course, look for a Coronation coincident with the next Electrical Exhibition, but Mr. Hirst's suggestion will, without doubt, materialise.

One of the most striking advances in the field of illumination is the growth of the movement characterised as illuminating engineering. Since the last Electrical Exhibition this movement has been born and has increased in vigour until at the present time it has become a power in the industry, but particularly so in the United States. The extraordinary zeal with which our American cousins take up any new thing is exemplified in the present position of illuminating engineering on the other side of the water. A considerable literature on the subject has sprung up and there are periodicals devoted solely to the advancement of improved methods of applying light units to practical purposes. We, on this side, have given a certain measure of support to a monthly publication, the "Illuminating Engineer" and this, as the organ of the Illuminating Engineering Society, is doing exceptionally useful work. The matter is one which is also engaging the attention of architects, and since the sympathies of this important profession have been enlisted the correct use of light in public buildings, private houses, picture galleries is more generally being insisted upon.

The improvements in the metal lamp have given a most extraordinary impetus to illuminating engineering. Some years ago when holophane reflectors were introduced they did not meet with the reception which they deserved because the carbon lamp did not give the ideal combination of light unit and shade. The metal lamp has changed all this and the Olympia Exhibition is a striking example of the progress made in holophane illumination. This may also be said of other forms of reflectors which have been introduced in order to obtain indirect lighting effects with a minimum of glare and a maximum of light distribution.

We hope that the efforts of the salesmen on the stands of the firms who have made a display with holophane lighting, particularly to visitors who are purely light users and are unconnected with the electrical industry, will bear good fruit in the immediate future. Educational work of this character is bound to produce good results. It should give the electricity consumer a better idea of what he can do with his light and it should assist him in his dealings with the electrical contractor who at the present time rather endeavours to force more light upon the consumer than he actually requires. These demonstrations should also be attended by electrical contractors who have a most important function to fulfil in that they act as intermediaries between light makers and light users. At the present time they have not sufficiently realised their responsibilities or opportunities in this connection. As we have just stated, their main object has been to get a consumer to put in as many lights as possible quite irrespective of their disposition, the effect they will have upon his eyes or, what is even more important, the influence they will exercise on his energy consumption. We think that it cannot be too strongly impressed upon the electrical contractor that the Electrical Exhibition at Olympia is a Mecca to which he should immediately and frequently resort. He will not have an opportunity for many years to come of studying at close quarters an aggregation of light units of all classes and their application to the requirements of light users. It seems a pity that the Illuminating Engineering Society did not seize the opportunity to arrange for one or two lectures by, say, Mr. Gaster or Mr. Francis Willcox to drive home the real lesson to the electrical contractor of the lighting developments of the Exhibition.

An Example of Office Lighting with Mazda Lamps.

It is quite impossible for us in the space at our disposal to give a full description of the good work which makers of arc lamps and metal lamps, fittings, signs and lighting accessories, are doing at Olympia. We reproduce a number of pages which are purely illustrative and which are intended to typify the latest advances in illuminating engineering. If these are studied in conjunction with the brief notes which we introduce of the actual displays of the exhibitors concerned we feel sure that some good will result.

SIGNS AND SIGN LIGHTING.

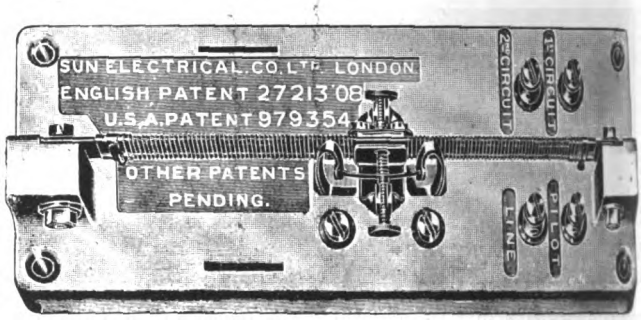
We are in the midst of a revolution in matters of signs and sign illumination. The Olympia Electrical Exhibition contains more novelties in signs and sign accessories than we could possibly hope to deal with in a full volume. It is a remarkable collection of the products of sign makers, and is also a striking testimony to the zeal and enterprise of this class of manufacturer. We can confidently commend the signs at Olympia to the notice of electrical contractors, central station engineers, architects, tradesmen, &c. The metal lamp is responsible for these changes in electric signs. Its brilliant light and high efficiency have raised the sign to such a level that it becomes an economic necessity for the tradesman, the restaurant and hotel proprietor, railway companies, theatres and cinematograph shows, and, in fact, for anyone who has to appeal to the public on the pavement.

A particularly noticeable item about the signs at Olympia is their artistic arrangement. There is a certain class of tradesman who does nothing except in a perfectly dignified manner. This type of customer is admirably catered for by the sign makers at Olympia. He is offered art metal signs which he hangs inside or outside his windows, and which, while he makes known to the passing public his products by means of the stencilled lettering of the face of the sign, he also uses the same lamps which illuminate this lettering to light the goods in his windows. This is a notable achievement, and is quite the latest thing in signs. It may be inspected in particulars at the stands of **Simplex Conduits, O. C. Hawkes (Ltd.)** and the **General Electric Co.**

We wish to specially emphasise the importance of this new reflecting sign, and the influence which it will undoubtedly exercise on methods of trade developing by illumination.

The box sign still holds its own for certain classes of advertising, and deservedly so. Many examples of this will be seen exhibited at Olympia, and their efficiency has been materially improved by the use of the metal lamp. An interesting development of this class of sign may be found on the stand of the **Credenda Signs Co.** This company is manufacturing illuminated signs on the Venner principle, which, as our readers are doubtless aware, makes use of a number of glass balls at the front of a box, inside which are a few metal lamps. The balls can be arranged to form any desired lettering or design. Many of these signs are to be seen in all parts of the country, and once seen they cannot very well be forgotten. The development to which we have just referred is the application of this principle to the outline illumination of well-known posters, for instance the type of coloured advertisement used by the railway companies. The Credenda Co.'s stand is fitted up for the display of these signs, and it is possible to demonstrate the effect of use both by day and night. The day effect is practically the same as the ordinary coloured printed poster. At night time the principal outlines of the subject of the poster are picked out in small beads of light. We think that there will be a big field for this class of sign, and we hope that the company will meet with a generous amount of support from the railways. This particular principle is readily applicable to flasher signs, and some fine specimens of these are on view at the Exhibition. If a series of different coloured lamps is used in the box enclosing the sign, the glass beads can be illuminated in these colours, and an extremely pleasing effect is produced. We are pleased to see that this particular sign has been taken up with a view to extending its applications, and judging by the many excellent examples which are displayed at the Exhibition the efforts of the company should meet with the success they deserve. The modern electric sign would be a very poor thing without efficient flashers or other devices for giving either coloured effects or intermittent lighting. The flasher may appear, at first sight, to be an extremely simple thing to manufacture. One only needs to walk up and down the main streets of London or our large provincial cities to see evidence in the many changes in signs of the practical utility of the modern flasher.

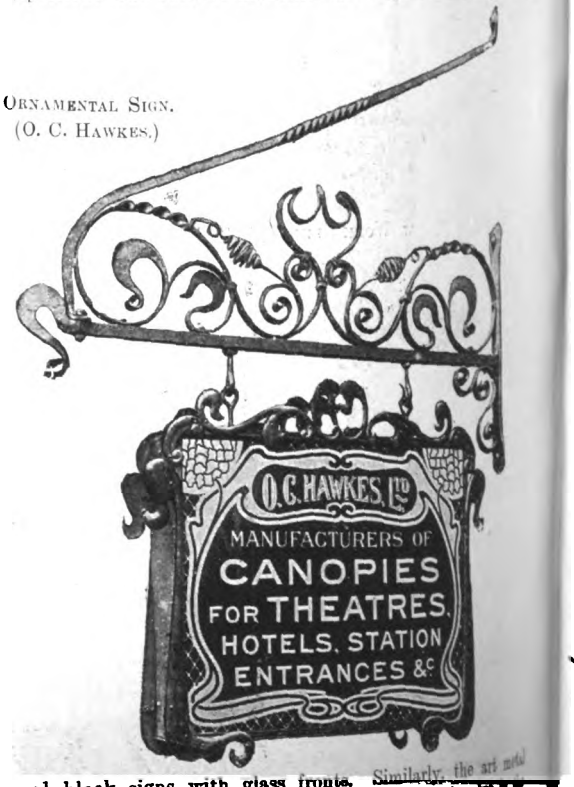
The Sun Electrical Co. has devoted a considerable amount of time and attention on the subject of sign accessories, and interested readers would find on their stand a remarkable collection of signs of all kinds, and also of sign accessories. On the three facias of the stand, changing signs have been erected which typify distinctive classes of signs standardised by the company. Over the main entrance to the exhibit is a light representation of the company's trade mark, viz., the sun itself. The orb is formed by a Holophane hemisphere which is powerfully illuminated from behind. Radiating from this central point are rays which are picked out with small lamps. By the action of a special flasher the "sun" is first switched



SUN NEW TWO-WAY THERMO-BLINK SIGN FLASHER.

on and the rays are then lighted up in circles which constantly widen until the limits of the sign are reached. After a few seconds illumination the "sun" goes out and the cycle of operations is repeated. The experience of this company with signs of various classes has been practically unique, and without prejudice to other sign makers, we may say that they are in a position to meet practically every requirement of the sign user.

The box sign is also well represented in the exhibit of **O. C. Hawkes.** This company has specialised in a class of sign which may be seen at practically every railway station not only in the Metropolis but also in the provinces. They carried out the large opal glass map signs of the Underground Railways in London, and these are exceptionally fine examples of their work. Here again we find a most comprehensive display of the sign maker's art. Day and night signs appear to be a speciality, and the effect produced when a sign is turned on, by comparison with the daylight effect, is usually surprising, not to say startling. The company has a large factory in Birmingham where they specialise in glass work of various kinds, and this experience has been of immense advantage to them in putting



ORNAMENTAL SIGN.
(O. C. HAWKES.)

forward block signs with glass fronts. Similarly, the art metal work experience of this maker has proved of great value in the combination of a good box sign with an artistic method of supporting it. A good sign can often be spoiled by an indifferent metal supporting scheme.

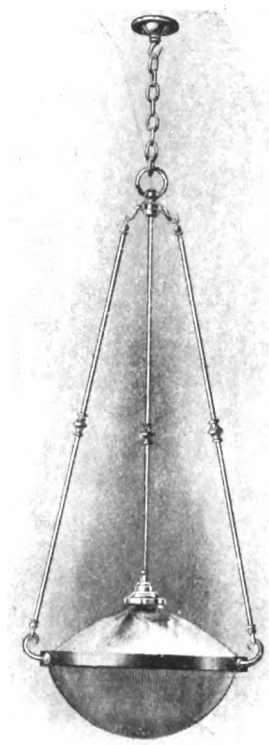
THE POPULARITY OF HOLOPHANE.

When holophane shades and reflectors were introduced a good many years ago, it was hoped that they would bring about a revolution in electric lighting. They were, however, brought out when the only small light unit was the carbon filament lamp, and it was not possible to show off the many advantages of holophane with a lamp of this character. Now that we have metal lamps which can be used in high candle-powers with economy to the light user, holophane, although it is practically the same in principle as before, is very different in practice. The metal lamp makers must be credited with this remarkable change, for it is unquestionably remarkable. The Olympia Electrical Exhibition is a model of good lighting in general, and of holophane illumination in particular. We speak, of course, mainly of the individual lighting of exhibits. Holophane is a thing which grows upon one. It may be likened to certain proprietary articles, once used always used.



A Tasteful Holophane Pendant.
(Simplex.)

The electrical contractor has not fully awakened to the business possibilities of holophane. He is, however, being stirred from his inactivity by the many enterprising firms who are making it their special business to prod him on. The general idea of holophane crystalises around **Holophane (Ltd.)**, who have arranged an attractive exhibit which is a practical and continuous demonstration of what holophane lighting is. It may be looked upon as showing the scientific and theoretical in holophane illumination as well as the practical, and the latter is also kept prominently in mind. By means of a suitably darkened room comparative results are obtained by switching on fittings with and without holophane reflectors. These reflectors can be handled and examined, so that, as the "showman" says, there is no deception. The man in the street, who is after all interested in things of this kind, has a tendency to believe that his leg is being pulled, and this characteristic, which is largely shared by we humans, is kept in mind by the organisers of the demonstrations at this particular stand. The holophane literature is replete with globes, shades and reflectors which can be used for every conceivable kind of fitting, pendants, electroliers, brackets, table and floor standards, ceiling lights, &c. The whole principle of holophane has been worked up into a complete illumination scheme which is now practically standardised and admits of every conceivable requirement of the light user being met. The essential feature of holophane is that not only is its principle scientifically correct, but it provides a practical embodiment of these principles. Holophane glassware generally is mechanically sound, and from the point of view of cleanliness it is hard to beat.

Another exhibit at Olympia which is admirably laid out for the display of holophane fittings is that of **Simplex Conduits (Ltd.)**. A conveniently arranged showroom attached to the stand is darkened, and the effect of any fittings can be demonstrated under actual working conditions. The variety of Simplex holophane fittings is too extensive to be covered in the space of this notice. Attention may, however, be specially directed to the pendant sphere and bowl fittings, which are highly ornamental in so far as their external appearance is concerned, and when lighted they furnish an effect so pleasant that the average householder to whom the fittings are shown for the first time usually goes into raptures over them. The bowls and spheres can be suspended by chains or rods from the ceiling, and the fitting can be adapted to any height of room. A particularly beautiful class of fitting is the holophane ceiling hemisphere. Every effort should be made to introduce this into new houses. The householder can make a selection from the plainest to the most artistic designs. Here again the illumination produced is restful; there is no glare and the glassware and its support can be cleaned with a minimum of difficulty. The holophane sphere and bowl have been made the centrepiece around which a large variety of special designs has been developed. These can be inspected at the Simplex stand. The same exhibit also includes what are known as holophane household glassware. These are hexagonal shades with special prisms which not only distribute the light horizontally, but also give good illumination in a vertical plane. They can be arranged for pendants or brackets, as the case may be, and the effect is pleasing in the extreme. Another beautiful form of holophane fitting is that in which the ordinary large silk shade is placed over either a holophane sphere or reflector bowl. Here again the distribution of light is soft and pleasing, and the advantages of the use of the shade are considerably enhanced. The Simplex Co. is doing an extensive business with holophane fittings and glassware, and has exceptional facilities at its disposal for supplying clients with general information on the subject.

The advantages of a combination of Tantalum and Onewatt lamps with holophane reflectors are being demonstrated at the stand of **Siemens Brothers Dynamo Works.** At the Manchester Electrical Exhibition an exceptionally fine display of "Tantaphane" was made by this company, and its effect has not been lost upon the industry. Since that time the Onewatt lamp, which has a high candle-power unit, has been introduced and has become very popular in combination with both large and small holophane shades.

A Small Size Reproduction of one of Siemens Prize Show Cards. The Design is by Mr. Sutton.

bowls, spheres and reflectors. The lighting of the Siemens exhibit has been largely carried out with holophane, Onewatt and Tantalum combinations, and visitors to this exhibit will be able to judge for themselves of the efficiency and effect of this scheme of lighting.

The general idea of holophane has permeated the electric lighting side of the industry, and it may be found embodied in one form or another on the stands of most of the fittings and lamp makers at the Exhibition, in particular, the **Edison & Swan Co., B.T.H. Co., Sunbeam Lamp Co., Brimsdown Lamp Works, Pope Lamps,** etc

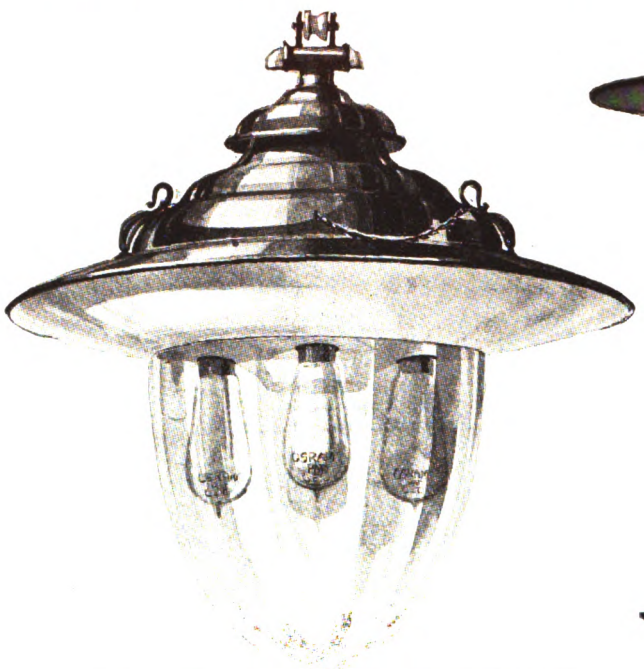
METAL LAMP CLUSTERS.

The durability and efficiency of the metal lamp have brought it into considerable use for street and shop lighting. Much of this class of illumination is now being carried out by either high candle-power metal lamps or clusters of metal lamps of medium candle-power from, say, 50 c.p. upwards. The development of fittings in which metal lamps are collected together to form a common source of light has been little short of remarkable during the past two years. The early efforts of Mr. Haydn Harrison in pointing out the advantages of the metal lamp for this class of service has been the means of rousing fittings makers to a sense of their duty in this direction. The result is shown in a remarkable manner at the Olympia Exhibition. Most of the lamp and fittings makers are displaying types of lanterns which should be the delight of the shopkeeper, the railway engineer, the factory owner, the central station engineer, and indeed almost every class of light user, though we mention these as coming first to mind. The enterprise of the last named in replacing carbon lamps by metal lamps in his street lighting lanterns has also given a marked impetus to the general application of the metal lamp to specific illumination. The shopkeeper is specially favoured in the matter of metal lamp lanterns and fittings at Olympia. If he is at present using old pattern arc lamps which require trimming frequently, and which give a poor return in light for the energy consumed, he should inspect the displays which various makers have put forward at the show. The high efficiency of these clusters is not as well understood or as widely known as it should be. We hope that the Exhibition will help to spread the light, in both senses of the term, in this respect. The shop tradesman is an important customer and presents a large section of the lamp and fittings purchasing public. We feel sure that manufacturers will be especially solicitous for his welfare at the Exhibition. By this we mean, pay him every attention in explaining the real meaning of these new fittings to him in his business.



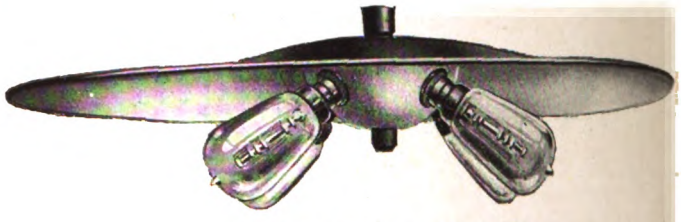
A Typical Cluster of Metal Lamps. (G.E.C.)

OSRAM-LAMPS

DRAKE & GORHAM EXHIBIT.

The exhibit of Messrs. Drake & Gorham is tastefully arranged with a display of electric-light fittings and domestic heating and electrical appliances. The exhibit is a little to the left of the entrance, and stands out prominently by reason of its brilliant display of lights. The fittings exhibited include all the most recent designs in pendant, bracket and ceiling lights, and most of the fittings are wired up and can be switched on individually or collectively. The exhibit has attracted considerable attention, especially so because the fittings and apparatus on view are displayed to best advantage. The combination of holophane glassware with metal lamps is given exceptional prominence, and visitors to the stand are given an opportunity of observing the pleasing illumination effects which can be obtained with these fittings. The advantages of properly arranged ceiling fittings and, in particular, the holophane hemisphere at ceiling level, are pointed out, this type of illuminating unit being appropriate for low ceilings where elaborate pendants cannot be introduced.

Electrical contractors and central station engineers will find interesting examples of shop lighting fittings, and especially of metal lamp clusters, which are offered by Messrs. Drake & Gorham for the use of tradesmen to replace the small pattern arc lamp. These fittings are of recent introduction, and they constitute a marked advance upon anything previously brought out. We understand that Messrs. Drake & Gorham have done a considerable amount of work in the improvement of shop illumination, and that they are prepared to advise tradesmen who have under consideration the question of the introduction of the high candle-power metal lamp or metal lamp clusters for use in the interior or exterior of their establishments. The Drake & Gorham fittings list is filled with numerous designs which have recently been developed with the idea of improving the illumination of domestic and trade establishments.



Metal Lamp Reflector Fitting.

Beautiful Examples of Drake & Gorham's Ceiling Fittings.

They have recognised the need for raising the standard of illumination in this direction, and are vigorously impressing upon light users how imperative it is that they should take advantage of the greater efficiency and economy of these advances in illuminating methods.

There is also a good arc lamp display on this exhibit, the Butt-flame lamp being especially in prominence. This is a type of lamp in which the mechanism has been reduced to the simplest, and the minimum number of parts, and at the same time the number of burning hours and general efficiency of the lamp are maintained. These lamps are shown under actual burning conditions, and visitors can, if they desire, inspect the internal mechanism.

As a conveniently arranged display of electric-light fittings and apparatus the exhibit of Messrs. Drake & Gorham may be regarded as one of the most striking in the Exhibition.

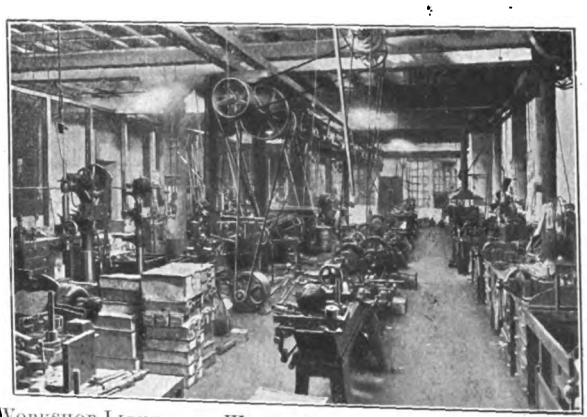
Mercury Vapour Lamps.

An exceptionally good display of the mercury vapour lamps is being made by several exhibitors at Olympia. The Westinghouse-Cooper-Hewitt Co. has a stand which is devoted entirely to this class of illuminant and we understand that it is attracting a considerable amount of attention. There are several new and interesting features which have been developed especially for the Exhibition, and are shown for the first time. In particular we may mention a special reflector which can be placed behind the tubular pattern of lamp, and it has the effect of adding red rays to the light emitted from the tube. This is an advantage because the use of the reflector does not entail an increased consumption of electrical energy and it means that a more pleasing light is available for special applications of the lamp. Hitherto the carbon lamp has been introduced in connection with the mercury vapour tube, but it has effected the electrical efficiency of the combination. The Westinghouse Silica lamp, which was introduced about 12 months ago, is given a prominent place in the exhibit. It has the special advantage of containing a short mercury tube, so that it can be enclosed in a globe of small diameter. The complete lamp also occupies a minimum of vertical space. The Silica lamp is automatic in operation, lighting up as soon as it is switched on. A large solenoid is used in the upper part of the lamp to give the effect of tilting the mercury tube. There is an automatic device which ensures the lamp burning on its correct polarity. The tubes are guaranteed by the makers for 1,000 hours' life, but the average life is in the neighbourhood of 3,000 hours. On a 250-volt circuit the lamp takes 3½ amperes and the mean hemispherical candle-power is over 3,000. With energy at 3d. per unit it will cost 1·1d. per hour, allowing for replacement of tubes, in a life of 2,000 hours. While on the subject of the mercury vapour lamp we may refer to the rectifier



Workshop Lighted by Westinghouse Cooper-Hewitt Lamps.

operating on the same principle, which is being shown at this exhibit. The rectifier itself has been known for many years, but it is only recently that the company has succeeded in producing a type which can be used in connection with projector lamps and which will strike up automatically as soon as the carbons of the arc lamp are brought into contact. This is an interesting development and it admits of cinematograph theatres converting the alternating-current supply to direct-current for the operation of the arc, in a very efficient manner. The rectifier is also shown in conjunction with mercury vapour lamps and here again possesses the same automatic features as the projector lamp pattern. From figures supplied by the company we gather that there is an actual saving of 35 per cent. in the use of these converters over the ordinary transformer which is used to reduce the supply voltage to that of the arc. This is worked out on the basis of six hours a day for 300 days and with energy at 5d. per unit. This remarkable claim should appeal to proprietors of picture palaces who will doubtless come to the Exhibition or send their electricians. We understand that the combined efficiency of the rectifier and mercury vapour lamp works out at a slightly better figure than the direct-current type of lamp, which is direct connected to its circuit. The efficiency of these mercury vapour lamps is in the neighbourhood of 0·25 watts per candle, and they may be connected on 110 or 250-volt circuits. Needless to say there is no trimming of the lamp required, so that for certain classes of lighting, where the colour of the light is not objected to, the lamp is eminently suitable on account of its intensive illumination.

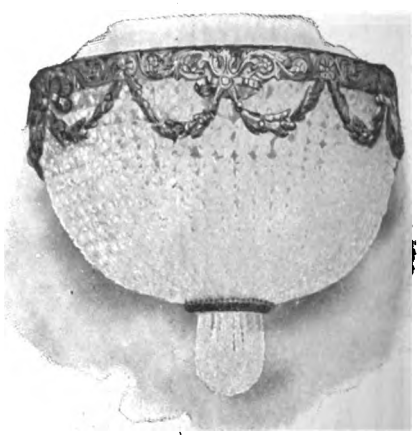
A Fittings Showroom.

One of the most neatly arranged showrooms in the Exhibition is that put up by Falk, Stadelmann & Co., a little to the left of the centre of the main hall. The idea of an exhibit on the lines of the large showrooms of this company in Farringdon-road has been admirably carried out. In particular the wiring has been carefully concealed so that the various panels on the walls and the fittings hung from the roof are models of neatness. Nothing looks worse in a showroom than the slovenly arrangement of the connecting wires. Most of the fittings on this stand are wired, and can be switched on collectively or individually.

From a detailed inspection of the exhibit we gather that the requirements of any class of fittings user can be met in the company's designs. Chased fittings of the most expensive character or plain or ornamental cast and bent metal designs are equally available. The exhibit includes typical examples of pendants, brackets, table lamps, floor standards, candle fittings, ceiling lights, &c. The

Falk, Stadelmann's Showroom.

selection of silk shades covers a wide range of designs and colours. This class of shade is most popular just now. Similarly the bead and glass tube shade is very pretty when used with metal lamps, and it figures prominently in this exhibit. It is a development of the crystal type of fitting which was all the rage during the days of candles and gas. By a strange vagary of fashion it is being revived to meet a growing demand. There are several tasteful examples in the Falk, Stadelmann exhibit. The popular taste is also admirably catered for, especially in fittings designed for flats and moderate-sized houses. Electric lighting is so much more common with this class of resident now that his needs require special attention.



Tasteful Crystal Fitting.

We would recommend interested contractors to visit the Falk Stadelmann showroom in the Exhibition, and if they can do so bring their friends and prospective customers with them.

We may also mention that the whole of this exhibit is lighted by Efesca metal lamps. This is a well-known tungsten lamp, having been on the market several years. It has a good reputation for durability of filament and efficiency, and it is supplied in large and small candle-power units for all voltages. Falk, Stadelmann offer special publicity facilities to electrical contractors for pushing the lamp, and will supply literature, show-cards and window attractions to assist in directing attention to the lamp.

B.T.-H. and Illumination.

The British Thomson-Houston Company has attracted considerable prominence to itself by the recent introduction of the Mazda drawn-wire tungsten filament lamp. When this lamp was put on the market we were given an opportunity of inspecting at the works at Rugby the facilities which the Company has at its disposal for the manufacture of this interesting lamp. We understand that the large factory at Rugby is now in full swing and that an exceptional demand is being experienced for this lamp. The wire filament reduces the risk of breakage in the early life of the lamp when it is transported from maker to dealer and from dealer to user. Its

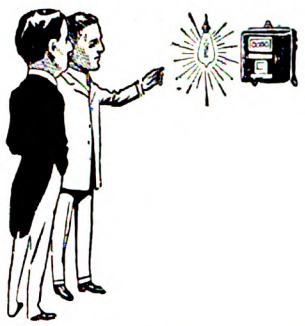
Examples of Mazdalux Reflectors.

extreme ductility and rigidity contribute to this desirable end. The B.T.-H. exhibit has been designed with the object of impressing on both the electrical contractor and the electric light consumer the necessity for method in the use of Mazda lamps in particular and electric light units in general. The stand is a striking object in this respect, and its arrangement reflects most creditably upon the management of the Company. Attention may be specially directed to the scheme of concealed lamp lighting in the roof of the stand. This is an example of illumination which can be introduced by architects who are able to start *de novo* in the illumination of a new building. It has, of course, a specific application, and must not be looked upon as suitable for general illumination.

At the time of our visit to the Rugby works we were impressed with the establishment by the B.T.-H. Co. of an illuminating engineering department. This has been placed under the charge of an engineer whose experience in this important field is, we believe, practically unique. Following upon the lines taken by well-known illuminating authorities in this country, on the Continent and in the United States, this department is developing data which cannot fail to be of the utmost assistance to architects, electrical contractors and light users generally. A scheme of this character must naturally progress slowly, and on this account certain types of illuminating devices have been developed which will meet the requirements of illumination which we in this country have undoubtedly made peculiarly our own. The science and theory of illumination are, of course, matters into which the architect and electrical contractor cannot possibly dip deeply. It is here where the assistance of the illuminating engineer is of value. He can place in the hands of the parties concerned efficient reflectors and fittings which will improve the general standard of illumination and serve to introduce on a broad basis the principles of efficient lighting. The B.T.-H. Mazdaliers are fittings of this class. Their application is practically without limit and they may be introduced with the certainty of giving satisfaction. The Mazdalux reflectors have been designed especially for use in trade and commercial lighting. They are shaped for shop-window purposes, for show-case lighting, and also for portable and table fittings. The reflector is solidly constructed of sheet steel, the outer surface is tastefully painted and the inner is treated with an aluminium coating which, while acting as an efficient diffuser, is unaffected by the atmosphere or dust, and, consequently, maintains its light-diffusing properties.

Illustrations of these Mazdalux reflectors are shown herewith. The shapes are the result of careful study and experiment, and each fulfils a particular function. This type of reflector has been found to combine the properties of a number of independent light-diffusing and dispersing devices. It has a wide field of utility, and information will be willingly furnished to interested contractors and central station engineers as to the many purposes for which Mazdalux can be used.

Through the courtesy of the company we were able to inspect a series of designs in new fittings, the object of which is to furnish a pleasing and comforting light with an entire absence of glare and with efficient distribution. These make use of inverted bowl reflectors and throw the light on to the ceiling, from which it is reflected into the room. The fittings form part of a general scheme of



"*You Find You Are Paying for Electricity*"

From a Mazda Lamp Leaflet.

illumination in which Mazda lamps are utilised as the light units. Many beautiful examples of this form of lighting exist in the States, and we hope that the illuminating engineering department of the B.T.-H. Co. will be able to impress its advantages upon light users in this country, with such modifications as may be necessary to suit English conditions. There are innumerable consumers of electricity who would welcome a variation from the pendant and bracket style of lighting, which has somehow or other become part and parcel of our home and commercial life. The illuminating engineer is here to break up these old ideas, and although it may be necessary for him to proceed slowly, if he goes about it in the right way he should achieve the object which he has in view.

A Striking Example of Reflected Lighting with Mazda Lamps.

Turning again to the exhibit of the B.T.-H. Co. at the Exhibition, we may specially remark upon the border lighting round the top of the stand and the mechanical reproduction of the company's poster, which is an imposing advertisement on the roof. The border sign is kept constantly on the "run" by means of a flasher, which switches out consecutive coloured lamps, and gives the effect of a coloured system of light passing round the stand. This is the only example of this kind of lighting in the Exhibition.

Digitized by Google

The strength lies here - in the filament

The strength of the Mazda Lamp is where the strength of a lamp should be—in the filament. The Mazda filament, instead of being in short, brittle lengths, is in one continuous drawn wire of **pure** Tungsten. This great success has only been achieved after years of painstaking laboratory work and repeated failures. Many scientists were of the opinion that it was impossible to render Tungsten sufficiently ductile for wire-drawing, owing to its brittleness, but it is now an accomplished fact, and we are telling the public of its great advantages.

FLAME ARC LAMP DEVELOPMENTS.

At the end of September last year, we published a special issue of this Supplement which was devoted exclusively to the subject of flame arc lamp progress. Since the issue of that special Supplement the position of the flame arc lamp has been advanced considerably in the industry, although the question of patents has considerably disturbed the composure of a number of manufacturers. Quite aside from the question of these patents, the flame arc lamp now takes up a position in which it comes in for a greater share of comparison than formerly with the metal lamp cluster. We lay ourselves open to correction in making this comparison, but for certain spheres of illumination there is no burking the fact that the competition of the metal lamp cluster and the flame arc has become, and is likely to become, much keener than heretofore. The presence and prospect of this competition have stimulated flame arc lamp makers to greater efforts in the development of their products, and we find at the Olympia Electrical Exhibition numerous examples of their enterprise in the introduction of improvements, both in the number and details of lamps. These are chiefly in the direction of the enclosure of the flame arc, and the Exhibition can show two new lamps, at least, of this design. The magazine type of flame lamp has also come in for a considerable share of attention. It is a pattern which

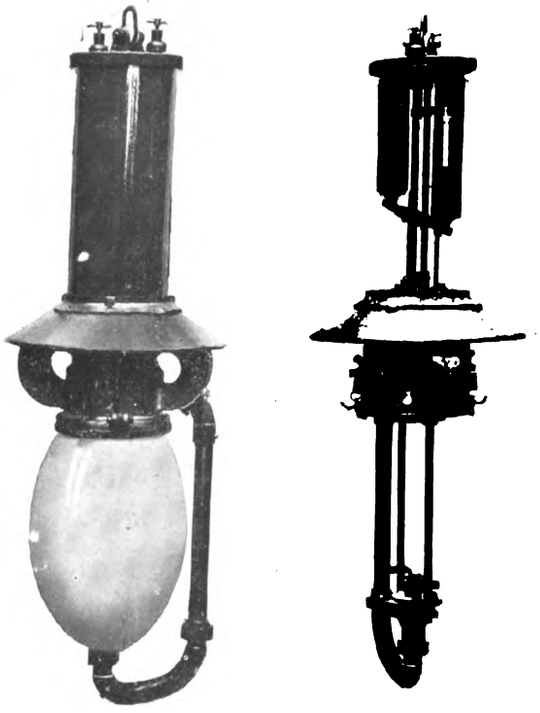
THEATRE LIGHTING WITH ARCTURUS LAMPS.
(BRITISH WESTINGHOUSE.)

enables the lamp maker to remove the essential difficulty with the flame arc, viz., the shortness of the life of the carbons. By the introduction of a number of pairs into a single lamp, and the provisions of automatic mechanism for the switching in of one of these after the consumption of its predecessor, the flame arc lamp user is furnished with a lamp which will burn up to 80 or even 100 hours.

As regards the field of utility of the flame arc, while this is likely to be narrowed down, as we have already suggested, by the competition of the metal lamp cluster and the high candle-power metal lamp, it still covers a wide area of street and open place lighting, and also shop fronts and large interiors. The efforts of the makers to simplify the lamp and also to prolong its burning life, added to the fact that the light user can obtain an efficiency as high as 8 candles per watt, should enable the flame arc lamp to keep its position in the world of illumination. It must not be thought that we are voicing the opinion that the flame arc lamp is in any sense on the decline. There are even now developments pending which should push the lamp farther ahead in the competition with other illuminants. It must still be regarded as the champion of electric lighting in comparison with high-pressure gas, and competition with gas must always be kept prominently in mind.

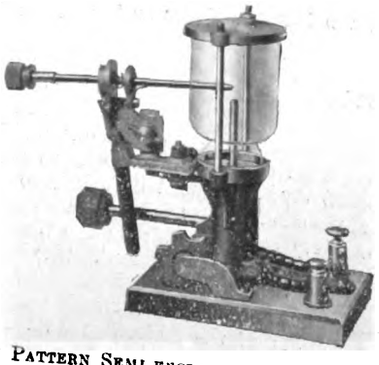
Turning now to the exhibits of arc lamps at Olympia, we may refer initially to the most noticeable novelties and improvements.

An interesting pattern of enclosed flame lamp is shown on the stand of the **Westminster Engineering Co.** An illustration of this



NEW WESTMINSTER ENCLOSED FLAME ARC LAMP.

is given herewith. The lamp is interesting on account of the fact that the cooling and condensing chamber for the gases from the arc is placed above the globe, and takes the shape of two circular channels, one on each side of the lamp. From the lower side of one of these channels a balancing pipe is taken to the lower portion of the globe, so as to balance any unevenness of pressure



NEW PATTERN SEMI-ENCLOSED PROJECTOR LAMP.

which may be created in the condensing chamber itself. This is clearly shown in the illustration. The positive carbon in this lamp is placed at the bottom, and it is a specially constructed carbon, having six concentrically arranged cores of a special metallic salts. The top carbon is solid. The control mechanism of the lamp is quite simple, and is on standard Westminster lines. Two of these lamps are shown

EXCELLO
FLAME ARC WITH UNIQUE
TWO YEARS' WARRANTY

Digitized by Google

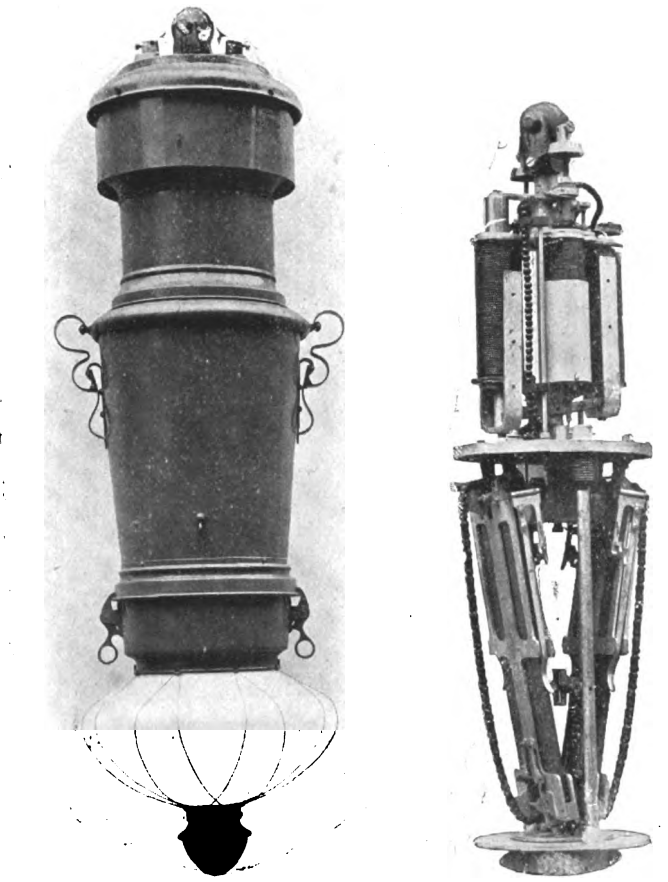
burning at the Exhibition, and they give out a powerful light of intense yellowy-white colour. At this same exhibit may be seen an interesting pattern of semi-enclosed projector arc lamp, for use in enlarging lanterns. This is illustrated herewith. The lamp is semi-automatic in action in that the arc is maintained over a considerable period, owing to its semi-enclosure. We understand that it will burn for upwards of half-an-hour without adjustment. A clear white light of from 300 to 600 candles can be obtained. The lamp measures 7 in. high by 4 in. wide by 7 in. long, and is wound for a standard current of 2½ amperes or up to 4½ amperes for autochrome signs. The lamp is suitable for alternating-current or direct-current circuits up to 250 volts.

Metroflam Lamps.

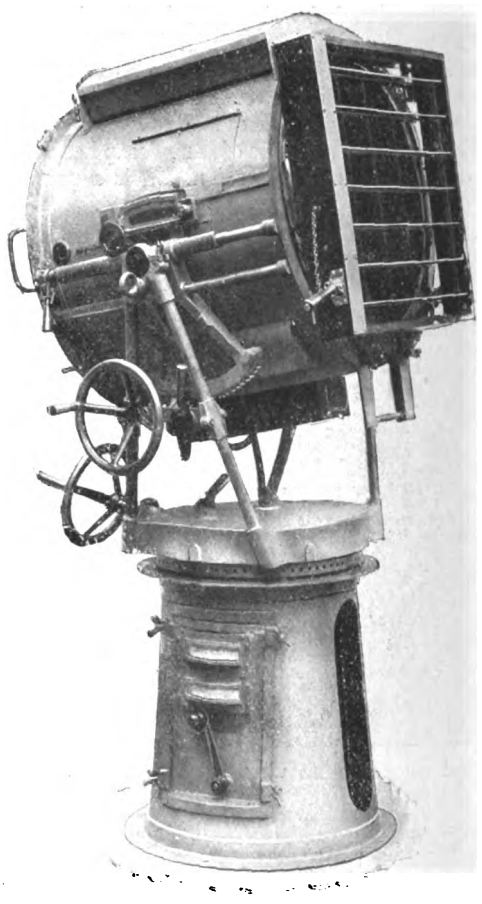
We have called attention in previous Exhibition issues to the displays of arc lighting which Messrs. Johnson & Phillips are making with their Metroflam lamp. This is one of the most interesting magazine lamps in the Exhibition, and since its introduction some 18 months ago has undergone considerable improvements. The burning life of the lamp is 80 hours and, what is the most important item of all to the makers themselves, the lamp has been installed in many places up and down the country for street, factory, railway, docks and shop lighting. Inexpensive carbons are used, and the pairs are burned down to the utmost limits. It should be noted that although the lamp is a magazine one, and it necessitates the changing over from one pair of carbons to another, this is accomplished without any interruption of the light source. The feed of the carbons and the changing from one pair to another is done in the direct-current lamp by solenoids; in the alternating-current lamp an induction motor field is introduced. The lamp is substantially made, and upkeep costs are negligible. Little attendance is needed and as the carbons are cheap the running expenses are very low. The working parts of the Metroflam D.C. lamp comprise chiefly a pair of carriers for containing the carbons, differential solenoids for striking and regulating the arc and a shunt coil system for feeding down the carbons, pair by pair, as they are consumed. The A.C. lamp is built on the same lines, but an induction motor feed is employed. Series burning lamps are provided with an auto-cutout and sub-resistance (or safety coil) to procure the continuity of the circuit, and these fittings are usually mounted within the lamp cover, so that each lamp is a complete unit. The non-extinction of the arc is secured by arranging that before one pair of carbons has ceased to burn another pair comes into contact. The arc is, therefore, at once formed between them, disappearing simultaneously from between the ends of the old pair.

Another feature of the Metroflam is its light diffusing globe, which has been patented. The globe not only distributes the light uniformly over a large area, but, in addition, remains unsoiled in use. The transparent appearance of the globe after a full run of 80 hours is most noticeable, and there is practically no diminution in candle-power at the end of this period.

The **Orb** is a simple and reliable single enclosed long-burning flame lamp, which has also been designed by Mr. James Brockie, and is shown on the same stand. It is of the shuntless type, a single series coil with a floating core for striking and regulating the arc. A simple and reliable non-slipping clutch is fitted together with a synchronous regulator, which renders it impossible for lamps burning in series to get "out of balance," so that the light emitted from all the lamps in a group is always of uniform intensity. The lamp is ornate in appearance, and looks equally finished either with or without a reflector. Both the A.C. and D.C. Orb lamps burn noiselessly and steadily, and are suitable for inside and outside use, and cheaper to run and maintain than metal lamps.



EXTERIOR AND INTERIOR VIEWS OF METROFLAM LAMP.



J. & P. SEARCHLIGHT PROJECTOR.

The projector lantern shown on the stand is a light steel drum, and its primary equipment consists of a 24 in. diameter silvered glass parabolic mirror and a combined automatic and hand-feed horizontal lamp arranged for working with a current of 80 amperes. The lamp is provided with a pair of main coils for striking the arc, and an independent coil for feeding the carbons together actuating through a ratchet gear a divided right and left hand screwed spindle and traversing nuts which engage with the carbon carriers. The automatic gear is thrown out of action for re-trimming or when operating the lamp by hand. A blow magnet is fitted for centring the arc to obtain steady burning and a well-shaped crater. One of the most recent contracts awarded to Messrs. Johnson & Phillips for an installation of this lamp was that at Manchester for the new scheme of arc and gas competition lighting. Also, the Great Central Railway Co. are installing them at their new Immingham Docks. We introduce illustrations showing the interior and exterior of this lamp which we are sure will be of interest. Readers will find numerous interesting Metroflam installations in London, particularly that in Cannon Street, where the lamps are suspended by span wires over the centre of the road.

The Angold Magazine Lamp.

Some notable improvements have been made in this lamp and in particular in the mechanism for controlling the descent and changing of the carbons. This operation is effected by a solenoid which is brought into circuit by a positive action carbon contact switch. This switch is itself controlled by the shunt and series solenoids of the lamp. The whole of this mechanism is highly ingenious and reflects great credit on the inventor. At the same time it is simple and reliable in its operation. The carbon feed is extremely gradual, a pair of phosphor-bronze toothed racks over which a reversing pawl is operated being used to give this nicety of control over the movement of the carbons. When the ends of the burning pair of carbons are pushed down into the economiser, the feed mechanism reverses and another pair of carbons is brought over these ends. The feeding downwards then continues, and when the burnt ends fall into the globe the following pair take up the arc in a few seconds. This means a practically uninterrupted burning of the lamp as long as the carbons last. The life is up to 95 hours, according to the current consumption of the lamp.

The current is carried through the case of the magazine to the carbons and pitting of the guides is avoided by providing a sliding surface which is virtually four thin lines against which the carbon presses uniformly. A weighted lever holds the lower end of the carbon securely in position. The two foregoing precautions prevent sparking in the magazine.

The economiser is of cast-iron and is hinged and held up by a simple catch ; it is therefore easily swung open for cleaning. In fact all the parts of the lamp are readily accessible. An ingenious method of sealing off the globe from the upper part of the lamp has been introduced. The base ring carrying the economiser has a machined surface on its under side and this is firmly pressed against a corresponding surface on the ring at the bottom of the lamp case ; this case is suspended on rods which are so jointed that a toggle action is introduced by which the pressure on the two surfaces just mentioned is obtained. The lamp is neat in appearance, and it is suitable for the usual burning conditions. A number of lamps are burning on the G.E.C. stand at the Exhibition and they are noticeable for the steadiness and brilliance of their light.

The General Electric Co. also show the Butt flame lamp, which is an ingenious lamp having a very simple control mechanism. There is a special stop, on which one of the carbons rests, and the feed mechanism is such that the carbon descends very gradually, carrying the other carbon also with it. There is no jumping of the arc on account of this gravity feed, consequently the light is maintained steady. The lamp is recommended for the lighting of shops, windows and similar places where a small pattern of flame is needed.

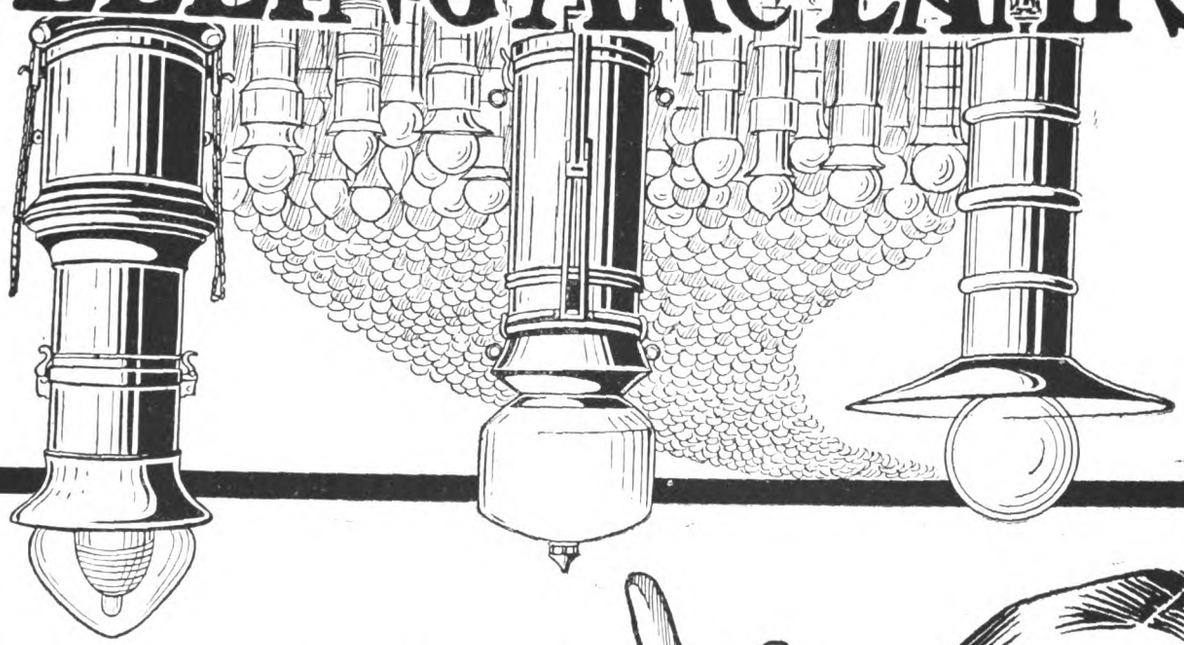
SELLING ARC LAMPS



What Lamp shall I push?

is a thought which is probably on your mind just now.

Look round at the various Arc Lamps at present on the market—carefully analyse their salient features, and it will not take you long to realise that

G.E.C. ARC LAMPS, *i.e.*

"BUTT" (Conta Patent) FLAME LAMP,

"ANGOLD" MAGAZINE FLAME LAMP

AND

"ANGOLD" ENCLOSED LAMP,

stand out prominently in front of all others in points of selling characteristics.

Points that count with the buyer are:—

(1) Reliability.
(2) Low Carbon Cost.
(3) Simplicity.
(4) Durability.
(5) Moderate Price.

—just the very features which have built up for G.E.C. ARC LAMPS their unequalled reputation!!

¶ If you faithfully describe G.E.C. Arc Lamps to your customer you will experience no difficulty in securing his order!!

¶ If you are not thoroughly acquainted with them ask us for fully descriptive leaflets—IT WILL PAY YOU TO KNOW THEM.

THE GENERAL ELECTRIC CO., Ltd.

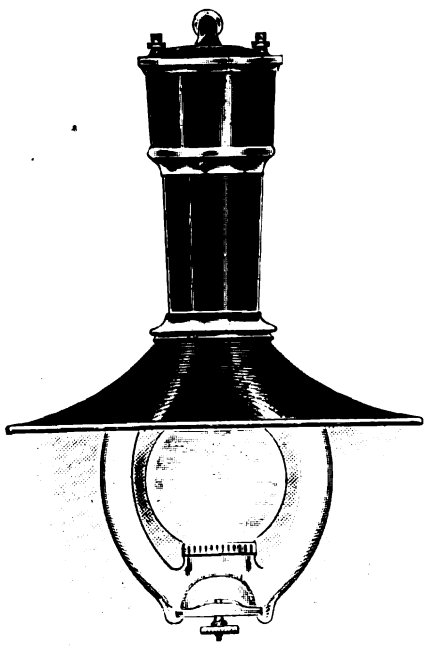
Jandus Regenerative Lamps.

The scheme adopted for the display of the Jandus lamp at Olympia has occasioned much favourable comment. A handsome fumed oak structure has been erected and surrounded by a heavy railing of the same material. The lamps themselves are let into panels in the corners of the exhibit, each pattern of lamp having a niche to itself. This arrangment allows of the inspection of each lamp without having one's attention attracted by surrounding objects. The Jandus Co., of course, specialise in one thing, and they appreciate the importance of "staging" correctly at an exhibition. The lamp itself retains all its good features, and is offered as a standard product with a minimum of working parts and a maximum of light efficiency and life. Since we last commented upon it, we understand that it has been widely taken up, and that its users are eminently satisfied with it. We may call our readers' attention particularly to the small pattern of Jandus lamp which is offered for certain classes of shop lighting, open spaces, factories, work rooms. It is a good light giver and is economical of energy.

The regenerative lamp gives a life of 70 to 120 hours. The number of burning hours is according to the particular adjustment of any one or series of lamps. Only one pair of vertical carbons is used per trim, and the carbons are mechanically strong and capable of withstanding rough handling. The efficiency of the lamp is nearly 8 candles per watt. A distinct advantage is obtained with the use of vertical carbons, as with a current as low as 5 amperes a candle-power of 4,000 is given off at an angle of 15 deg. below the horizontal. The light possesses valuable penetrative qualities, and is very suitable for murky or foggy weather. As the top carbon has a vertical feed it has been possible to do away with all clock-work mechanism. A further feature of the lamp is the flexibility of the arc, which allows it to be adjusted to suit voltages between very wide limits.



Jandus Regenerative Arc Lamp.

The small consumption lamp, to which we have just referred, is adjusted to consume only 250 watts, including loss in line resistance. The candle-power is 1,800 to 2,000 c.p. maximum and (as in all Jandus regenerative lamps) is given off at an angle of about 15 deg. below the horizontal. The lamp shows marked economies over the enclosed arc or the high candle-power metal lamp. As is well known the ordinary type of single enclosure arc lamp burns 60 to 70 hours, and gives 800 to 1,000 c.p., taking 500 watts approximately. Compared with this the small consumption regenerative lamp, burning 100 hours, gives double the candle-power for half the consumption of the single enclosure lamp. Again, a 200 c.p. metal lamp takes 250 watts approximately, while the regenerative lamp for the same consumption gives approximately 10 times the candle-power. It will be seen from these examples how the regenerative lamp can be adjusted to meet nearly every possible circuit condition.

The regenerative lamp has now been adopted for street lighting, dock lighting, railways, factories, collieries, ironworks, &c., and in having it on the market the Jandus Company have a lamp which is proving itself a boon to all who have adopted it. From the many users, reports are constantly coming in that after experience with the lamp the following points have been most pronouced and effectively proved :—

1. In plant or reduction in bulk supply for lighting.
2. In labour costs.
3. In carbon costs.
4. Adaptability and high efficiency.

The works of the Jandus Company are situated in Holloway, close at hand, and visitors to the Exhibition can make arrangements for inspecting the actual manufacture of the regenerative lamp at any time.

Magnetite Arc Lamps.

The magnetite arc lamp is recommended for lighting areas where a large volume of light is desired, and is adapted for lighting machine shops, foundries, factory yards and places where the slight fumes given off by the lamp are not objectionable. The most striking feature is the character of the arc used, this being formed between an upper electrode consisting of a short copper bar and the lower electrode which is composed of an iron composite called magnetite. The upper electrode always remains in the same fixed position, the feeding and regulating being done through the lower electrode which moves in a vertical direction. Since the upper electrode remains stationary, the arc always remains in the same focal position. In feeding, the lower or negative electrode is drawn upward by a pair of shunt magnets until it strikes the positive electrode; the magnets are then short-circuited by an automatic series cutout, and allow the lower electrode to fall back into normal position, thereby forming the arc. When the lamp is operating, the steadying resistance and small series cutout only are in circuit with the arc. The steadying resistance is of the well-known edgewise wound type. The casing is of solid copper with black oxidised copper finish. Flexible cables have been substituted in place of binding posts, so no trouble will be experienced with the lamp from metallic dust.

The lamps give an ideal distribution of light which is maintained throughout the life of the electrodes. Inside the globe and directly above the arc is located a small reflector 11 in. diameter of sheet steel, and of the well-known inverted concentric type. With the magnetite arc most of the light is emitted by the arc stream proper in a horizontal direction, this being an important aid to good diffusion. By placing a reflector above the arc, part of the light is concentrated directly beneath the lamp, so that the maximum light and an even distribution are obtained on the working plane. Special reflectors can be furnished to throw the maximum light in either a horizontal or a vertical direction. This makes it possible to instal the lamps in low or high positions, and secure a satisfactory light distribution.

At 4 amperes the efficiency is 0·758 watt per mean hemispherical candle-power, and at 6·5 amperes it is 0·493; this, it will be seen, is remarkably high efficiency for a lamp of this character. The cost of the upper electrode can be considered negligible, as it has a life of between 6,000 and 8,000 hours at 4 amperes, and 1,000 to 2,000 hours at 6·5 amperes, with a comparatively small renewal cost. In trimming, only the lower electrode requires renewing, and, as this has a life of from 175 to 200 hours at 4 amperes, and 100 to 130 hours at 6·5 amperes, the expense of trimming is relatively low. The magnetite lamp is suitable for use on continuous circuits only. Single lamps can be operated on 100 120 volts; a subsitutional resistance is not necessary for these lamps. Lamps can be operated two in series on 200 150 volts or five in series on 500 volts, but a substitutional resistance mustbe used with every lamp when run in series. Lamps for both single multiple and series running can be supplied for either 4 or 6·5 amperes. The lamp is made by the B.T.-H. Co., as it is shown in the three above illustrations.

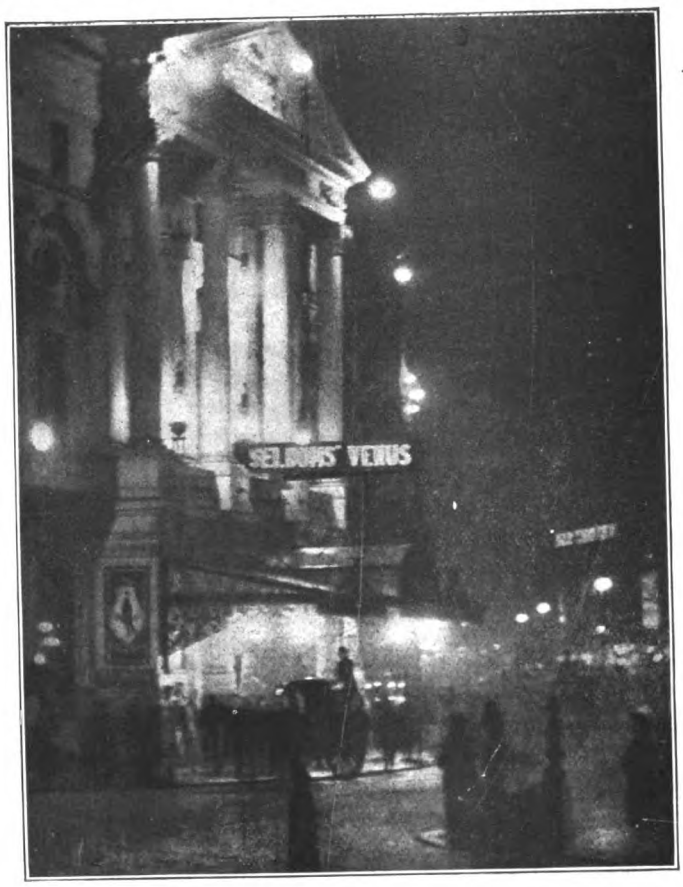
Excello Arc Lamps.

The exhibit of the Union Electric Co. may very well be termed a blaze of light. In the centre of the stand is an imposing structure surmounted by four bracket posts from which Excello arc lamps are hung. There are eight Excello lamps in all on the stand, four running with a current of 12 amperes on a direct-current circuit and four with the same current on a 50 cycle alternating-current circuit. All these lamps are fitted with the well-known deposit free cover and their burning life is from 16 to 18 hours with a single pair of carbons. Arrangements have been made for the display of the mechanism of these lamps on the stand so that visitors will have every facility for the closest possible inspection. Users of light who require to illuminate large open spaces will be interested in the Excello dioptric globe. This was introduced some years ago and has been found of great value in improving the horizontal distribution of light from the lamp. The dioptric globe is used in lamps for street, yard, railway depot, dock and wharf lighting, and in any situation where the lamps require to be spaced at considerable distances. We have described the Excello arc lamp so frequently that we feel that it is not necessary for us to enter into further details upon its many excellent points. It enjoys probably a greater vogue than any other type of lamp and may be seen almost everywhere utilised for an infinite variety of



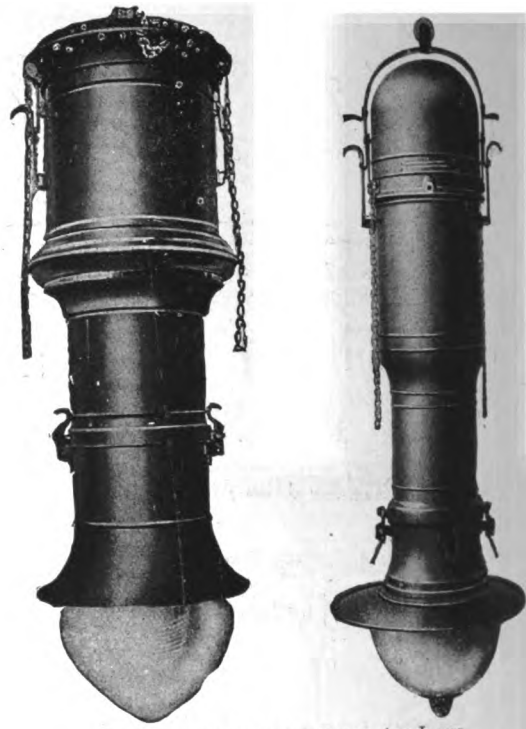
A Beautiful Lighting Effect with Excello Lamps.

lighting purposes. The parts of the lamps are all standardised and made strictly to gauge, so that they are accurate fitting and interchangeable.

The general display of enclosed lamps by the Union Electric Co. is also of interest. We may mention in particular the Koh-i-Noor pattern, there being six of these shown on the stand. With the normal running current of 5 amperes these lamps have an approximate burning life of 25 to 30 hours per trim. The lamps are suitable for direct-current and alternating-current circuits and may be fitted with a variety of different covers, making them suitable for indoor or outdoor lighting.

The Union Electric Co. has made a special study of the subject of indirect and semi-direct lighting with arc lamps, both of the open, enclosed and flame pattern. We have seen many beautiful examples of this class of lighting and it should specially commend itself to architects who have the design of new buildings in hand or the re-modelling of old buildings. Similarly, illuminating engineers should take special note of its many advantages. The circumstances under which it can be applied are of a special character, but where they are exactly suitable it is difficult to conceive of a more beautiful result.

The visitor to the Exhibition is further reminded of the presence of arc lighting specialities on the Union Electric Co.'s stand by the projector which is in constant operation during the evening. The particular pattern shown has a mirror 24 in. in diameter and the

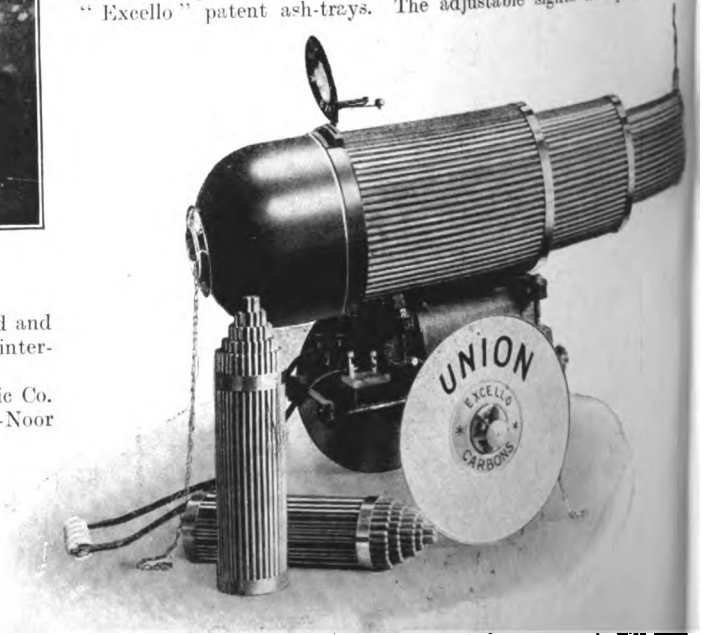


Examples of Excello Flame Arc Lamps.

lamp has an automatic feed controlled by differentially wound magnets. The projector is of a pattern which has been supplied to comply with War Office regulations, Admiralty regulations, and the conditions of the Suez Canal Commissioners. All the parts of the lamp are readily accessible. Provision is made for the inspection of the arc through obscured sight glasses.

Excello Ordnance.

The Union Electric Co. has just turned out from its works a piece of artillery which should be useful for the coming lighting campaign. This is on show at the Exhibition, and consists of a large-bore field gun, built entirely of "Excello" parts, accessories and carbons. The breach end is an "Excello" lamp cap; the carriage is an auto-transformer, supported on lamp-reflector wheels, the hubs of which are "Excello" patent ash-trays. The adjustable sights are quite a



Excello Carbons.

feature, the fore-sight being entirely different from anything now in use by any Government. The barrel is composed of entirely "Excello" patent carbons, as also are the projectiles, which are calculated to pierce an armour of prejudice of hitherto unheard-of thickness.

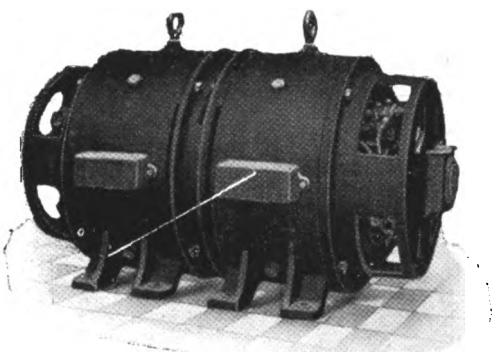
OLYMPIA EXHIBITION.—*Continued.*

Wright & Wood. (Nos. 129, 130.)

The exhibit of Messrs. Wright & Wood, dynamo and motor manufacturers, Halifax, is combined with that of Messrs. Berry, Skinner & Co. The Wright & Wood machines exhibited are of interest particularly as several new types have been introduced. We may mention in particular the duplex type cinematograph motor-generator. This is designed with the motor operating on a 460-volt circuit, and the generator giving 48 amperes at 65 volts, the speed of the unit being 1,100 revs. per min. The machine has only two bearings, and the overall dimensions have been considerably cut down. With this arrangement also the weight of the complete set is much less than if four bearings were employed. There is also, of course, less



Wright & Wood Compact Motor Generator.

maintenance cost and greater rigidity. The machine is made in 14 standard sizes, and we give an illustration of it herewith. Another interesting machine is a rotary converter fitted with ball bearings. This runs on 110-volt direct current, and furnishes alternating-current energy of 50 cycles at 71 volts, the output being 500 watts and the speed 1,500 revs. per min. A ¼ H.P. 2,000 revs. per min. plate polisher is another interesting machine and also a tiny hydro-electric set, which has an output of 75 watts, and is suitable for small installations having a low voltage lighting system. The company's cork pulleys should be inspected. These are shown in sizes from 4 in. diameter upwards, and are said to be lighter, to have no slip and wear and a larger transmission ratio. The exhibit is accompanied by a number of motor-starting devices.

Marryat & Place. (No. 150.)

This firm has secured a site in the centre of the main hall, and are erecting one of their latest pattern automatic electric lifts on a steel structure reaching to a height of 50 ft. They claim to have developed the automatic electric lift from the electrical side as no other firm has done, and have profited by this experience in mechanical details. The difficulty with push-button lifts has been that with a brake of constant strength, the floor levelling varies according to the load—that is to say, when travelling with light load the car will stop a little above floor level, and when travelling with heavy load it will stop somewhat below floor level. This floor levelling error increases with the speed of the lift. To get over this difficulty, manufacturers have contrived various floor finding switches fitted in the well.

The M. & P. arrangement gets oper the difficulty without the aid of any well switches, the whole apparatus being self-contained and fitted either at the top or bottom of the well. It is thus possible to run lifts at three to four times the speeds previously possible with automatic control. The wiring and erecting costs are greatly reduced and the whole apparatus rendered much more simple and reliable than anything which has been before put upon the market. The lift exhibited is equipped with both push-button and car-switch control, together with a two-speed apparatus, the latter being a great convenience in places where it is sometimes required to operate the lift slowly for convenience of nervous or invalid people, and at other times rapidly for general business.

H. WEIDMANN,

RAPPERSWIL, SWITZERLAND,

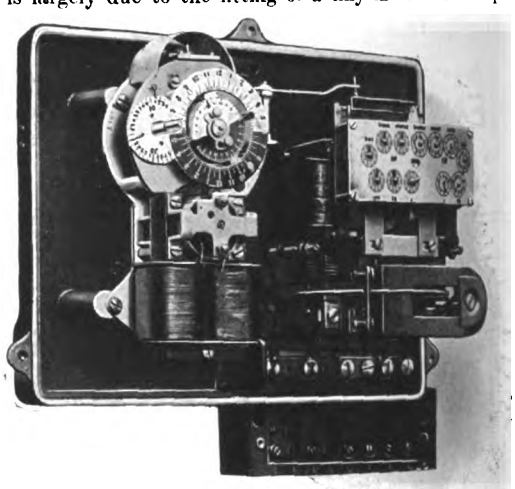
FOR

Presspahn and Insulating Material.

(See larger Advt. last week.)

Bat Meter Co. (No. 83.)

The experience of this company in the manufacture of electricity meters is demonstrated by the variety of types which they exhibit. One of the most noticeable instruments is a watt-hour meter of 2,000-amperes capacity with the shunt which carries a portion of the load. The meter is made up of a disc-shaped rotor, two flat field coils, two compound coils, a regulating coil with an adjusting iron core, and a pair of detachable silver brushes. There is no iron in the field or rotor and the meter can be used on alternating current or direct-current circuits. We understand the starting current is low and that the meter will register accurately on less than $\frac{1}{500}$th part of full load. This is largely due to the fitting of a tiny motor which imparts a



Bat Two-rate Meter.

rocking action to the brushes and counterbalances their friction with the commutator. The Bat two-rate mechanism should also be inspected and also an ampere-hour meter of the mercury type which the company has only recently placed on the market. It is stated that the temperature error, which is usually high in mercury meters, has been considerably reduced in this new pattern. It is said to be about 1 per cent. to 2 per cent. for 20°F.

IN THE GALLERY.

Although the bulk of the exhibitors are stationed in the body of the hall, there is a good show in the gallery, where upwards of 50 firms are showing.

The Electric Home. (No. 280.)

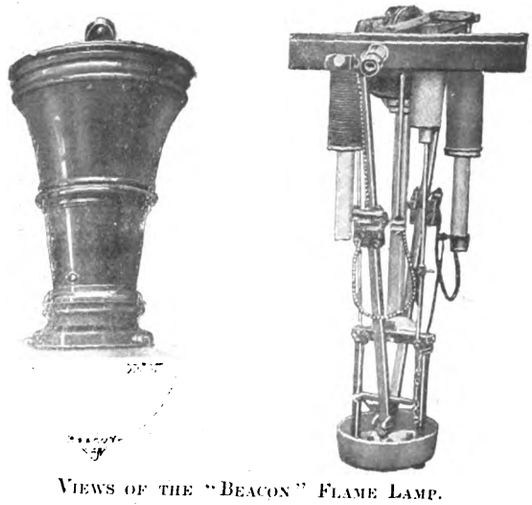
Messrs. John Barker & Co.'s "Electric Home" occupies the whole length of the gallery at the opposite end to the Addison-road entrance. The company has exceptional facilities for a display of this character, and has grouped in the various rooms of the home a fine collection of furniture, pictures, &c., which act as a suitable background against which to display various kinds of electric fittings and every conceivable type of domestic electrical appliance. The show is one which will not fail to attract the public, and the immediate proximity of a large number of easy chairs in which to rest should assist materially in bringing visitors to this exhibit.

Immediately adjoining it is a small stand of the **Kennedy Patent Bending Machine Co.**, which is a subsidiary of John Barker & Co., and which makes an effective display of Mr. Kennedy's well-known machine for bending steel and other conduits.

Digitized by Google

Beacon Flame Lamps.

The exhibit of Engineering & Arc Lamps (Ltd.) (stand 327, Gallery) comprises a display of Beacon and Sunrae flame arc lamps. The stand gives on to the gallery rail, and advantage has been taken of this fact to show a full blaze of "Beacons" to the public in the hall below and the gallery opposite. By this means the exhibit can readily be picked out from the main avenue of the Exhibition. In the midst of a fine display of arc lamps of all kinds, the outstanding feature of the exhibit is undoubtedly the Beacon flame lamp. The mechanism of this is so compact that it occupies a squat annular space at the top of the lamp case, and considerably reduces the overall length. The feed of the carbons (which are of the usual diverging type) is effected by a toothed wheel, gravity driven, but controlled in its rotation by a simple pawl, which is acted on by the differential solenoids. The net result is a tooth by tooth feed which is extremely gradual. In the double carbon lamp there is only a single toothed wheel to control the feed of both pairs, there being a clever throw-over device which comes into action as soon as one



Views of the "Beacon" Flame Lamp.

pair of carbons is burned out. Here, again, as with the single carbon lamp, the feed of each pair of carbons is most sensitive. Electrical men interested in the flame lamp should see the construction of the "Beacon" lamp. The exhibit will well repay a visit. The lamp has deposit free cover, and is offered with a three years' guarantee.

An exhibit of Attractor signs is also being made at this stand. The sign is fitted with an electromagnetic tapper, which knocks on the glass of the sign and positively compels attention. As soon as the passer-by has looked round the sign is lighted up, giving visual evidence of its presence and also its mission. Needless to say, these lamps and signs are of British manufacture throughout.

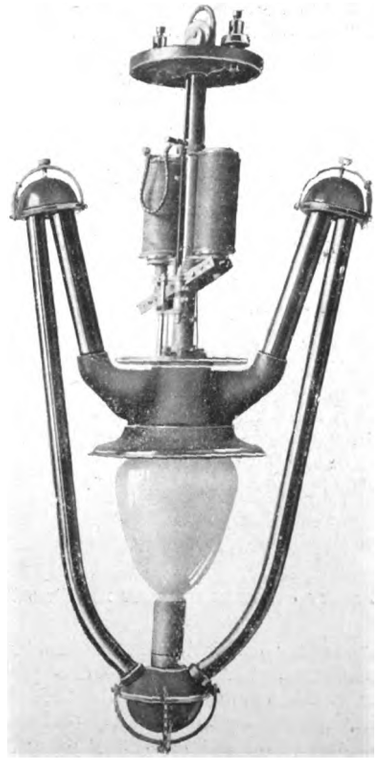
Electric & Ordnance Accessories Co.

The well-known Victor arc lamps developed by the Electric & Ordnance Accessories Co. are being shown at their Olympia exhibit. The Victor flame lamp is one in which a simple clutch mechanism controls the descent of the carbons, and there is an entire absence of clockwork or complicated mechanism. The carbons are placed at a diverging angle above the arc, and are enclosed in tubes which pass up through the controlling solenoids. The lamps are specially recommended for open spaces and factory lighting, and we understand enjoy considerable vogue. They are being exhibited under actual burning conditions at Olympia, and can be inspected in detail.

Hope's "Bi-Metal" Fuse Wire.

In the event of any misunderstanding having arisen, we are asked to point out that this new fuse wire is Mr. Vernon Hope's invention, and the patent is owned by Messrs. Parmiter, Hope & Sugden, of Hulme Electrical Works, Manchester. The fuse wire is manufactured by Simplex Conduits, Ltd., and sold by them, under licence, at the same price as the patentees.

The Abbey Electric Co. has on view, for the first time publicly, a flame arc lamp of an interesting pattern, which employs a special form of hollow carbon for one of the electrodes. The appearance of the lamp is shown in the adjoining illustration. It will be noticed that there is, immediately above the globe, a large collecting chamber for the gases from the arc. This connects on each side with a detachable elbow to which down tubes, leading to the cooling chamber at the bottom of the globe, are connected. The life of the lamp is 30 to 40 hours with one pair of candles. The efficiency of the lamp is stated to be 6 candles per watt, and the cost of the carbons ½d. per hour. The mechanism is confined to shunt and series solenoids, and there is no clockwork. The light emitted is of a pleasing colour, and appears to be quite steady and uniform; the carbons are inexpensive and the makers state that they will stand



Abbey Enclosed Flame Lamp.

a considerable amount of handling, also that when left in the open air they do not absorb moisture. The lamp is inexpensive and is of British manufacture throughout.

Sunbeam Lamp Co. (Nos. 55, 68.)

Wire-type tungsten lamps are among the novelties of this exhibit. The company claims that these are as strong as tungsten wire, and that the filament is in one continuous length, so that jointing at the supports is entirely dispensed with. The company hope to be able to meet the undoubted demand for a lamp of this pattern, and state that the economy will be the same as that of the squirted tungsten lamps. A prominent display is made of the latter, and they are shown ranging in sizes from the small battery type to those of 1,000 c.p.

A Pretty Sunbeam Bracket for Two Lights.

The exhibit is tastefully arranged, and an item of interest is the shape employed for the office. This is a portion of a sphere, the outside of which is represented as a map of the world. This globe design figures prominently in the company's advertising, and its introduction into the scheme of the stand has been very cleverly arranged. The Sunbeam Co. is noted for its supplies of accessories and fittings, and these will be found in some profusion on the stand. Among the electrical novelties is an illuminated device for calling cabs off the rank. We may also mention the special display which is being made of the "Lux" candle.

Edison & Swan.

The display of electric light fittings for which the Edison & Swan Co. are famous is divided between two stands at the far end of the main hall. The exhibit has been tastefully arranged, and there is a great variety of fittings on view. Pendants, electroliers, brackets, standards, candle fittings, &c., are presented in great profusion. The scheme of lighting has been carefully carried out, and harmonises with the grouping of the fittings. The company's fittings designs cover a wide range of tastes, and will be found to meet the requirements of practically all pockets. It is possible to make arrangements with the Ediswan illuminating department to supply fittings to harmonise with furniture and decorations. The use of method in illuminating schemes is now becoming more general, and the facilities offered by the Edison & Swan Co. should be taken advantage of.

The whole of the illumination of the two stands is carried out by Royal Ediswan metal lamps. These are of the squirted tungsten type, and are made in the usual sizes and standard voltages. The high candle-power lamps are items of considerable interest. These are made in sizes up to 1,000 c.p. per lamp. We understand that they are being taken up widely for street and shop lighting.

Aegma Lamps.

The metal lamps made by the Electrical Co. are well known under the trade name "Aegma," and enjoy a considerable vogue. The lamps have been on the market for some years, and the makers have utilised every effort to keep the standard of illumination and efficiency at a high level. Aegma lamps are of the squirted tungsten filament type, and are supplied in all standard voltages and candle-powers. They are widely used for street lighting, and in this connection are employed in ordinary or special lanterns. We understand that the Aegma lamp has been adopted for this purpose because of its long life and ability to resist vibration.

Multax Lamps.

The Globe Electric Co. is showing a number of Multax lamps at Olympia. We give an illustration of the stand at night, showing the arc lamps lighted up. We may remind our readers that in the Multax lamp a special form of carbon known as the "bridge-core" type is employed. This has been found to considerably prolong the life of the lamp, and it also has a steadying effect on the arc. The makers state that 100 hours' burning can be obtained with a single pair of carbons. The lamp is suitable for the usual circuit conditions and may be employed on A.C. or D.C. circuits. The general details of the mechanism of the lamp and sections of the special carbons employed are shown at the exhibit. The Multax lamp has been on the market for some time, and the makers can point to a large number of interesting installations in which it is giving complete satisfaction. Contractors and central station engineers should take an opportunity of visiting this interesting exhibit.

THREE YEARS' PROGRESS.

Since the publication of the first MINING ISSUE of THE ELECTRICIAN, three years ago, remarkable progress has been made in the application of electrical energy to the operation of mining plant and machinery. This progressive movement has been practically world-wide, and in particular we have to record a gratifying advancement in the mines and collieries of this country. In the present issue we have endeavoured to collate a quantity of valuable data and information bearing upon the present position of Electric Power in Mining; and we think that the special articles, each of which deals with a specific branch of the subject, together with the descriptions of modern electrical mining plant and equipment, will show what rapid strides have been made in every direction during the past three years.

The progress of electricity in mining has been unfortunately hampered by several disastrous accidents. Some of these have been due to causes quite outside electrical operations, but, on the other hand, some have been more or less directly due to the failure of that part of the equipment. When new apparatus is first introduced into a place like a mine, accidents are liable to happen, partly owing to lack of knowledge of the conditions under which the apparatus has to work, and partly to unfamiliarity with its use on the part of the men. Such accidents can, of course, be avoided to a certain extent by carefully prepared rules and regulations.

These have now been framed. Soon after our last Mining Issue was published the Home Office appointed a small committee to inquire how the existing Mining Regulations might be brought up to date and rendered applicable to modern electrical practice. Revised Rules have recently been published, and their scope is dealt with in a special article in this issue.

The new Rules are, we believe, the result of co-operation between the Home Office, Mine Owners and Plant Manufacturers. This is a logical way to set to work, for, taking the case of the switchgear manufacturers, as Mr. CLOTHIER points out, they have made many experiments to discover the best type of plant for the purpose of the numerous mining operations to which electricity can be economically and safely applied. Such co-operation can lead only to the production of apparatus best suited for the varying conditions to be met with in mines. The new Rules are concerned essentially with matters of safety, which are all-important, and in this connection the articles by Prof. W. M. THORNTON and Mr. H. J. S. HEATHER will be read with interest; they differ materially in the points of view from which they are written and refer to very different conditions of mining work.

As showing the extreme variability of the conditions that exist in mines, we may call attention to the arguments in Mr. HEATHER'S article which go to prove that earthing the neutral in South African mines is often extremely dangerous owing to the dryness of the rocks. This is directly

Digitized by Google

opposed to our own practice, because moisture is more generally present in mines in this country.

An event of considerable importance which we can now place on record is the linking-up of the large steam turbo-electric power stations on the North-East Coast, principally with the object of giving a cheap power supply to the collieries of Northumberland and Durham. This is a progressive movement which we should like to see spread to other coalfields in this country. It has the effect of relieving the colliery owner of the initial cost and responsibility of installing plant for the generation of power for his own collieries. In the Northumberland and Durham and other areas where the Power Supply Company can support the transmission lines with large generating units, the effect has been to encourage the installation of electric winders and large haulage gear without flywheel storage or load equalising motor generators. This, again, is an economy for the colliery owner. The points in favour of bulk supply to collieries are dealt with by Mr. W. B. WOODHOUSE, of the Yorkshire Electric Power Co., in a special article.

At the same time there are groups of collieries in which small generating plants have been used for some years past at the pit head, supplying energy for light and power to a single pit. By the employment of modern steam turbo-generating plant, it is possible to give the same efficient supply to a group of collieries which are under a single management or ownership, and the arguments for such a concentration of plant are put forward by Mr. W. E. CHAPPELL in this issue. These conditions apply, of course, to a district in which a bulk service of power is not available. On the other hand, there is still a good case to be made for the use of steam turbo-electric plant at the pit head of large collieries. The improvements in steam turbines, both of the high, medium and exhaust-pressure types have entirely changed the aspect of this problem. Mr. W. B. SHAW deals with this subject in a special article, and here again the argument must be considered as applying to a district in which a cheap supply of power is not yet available.

In our first Mining Issue, we devoted a considerable amount of space to the design, construction and operation of electric-winding engines. In the present issue we are able to publish an article by Mr. GERALD HOOGHWINKEL, dealing with the progress of electric winding in England since that time. Complaint is often made that the steam system is much the simpler, but, although an electric winder requires the use of a certain amount of subsidiary apparatus, this lack of simplicity is not really a disadvantage. That electric winding is making considerable progress will be gathered from the Tables which we give in another part of this issue. It is very often thought that there are quite few mines where such winders are installed, but this, it will be gathered, is not by any means the case. It may be definitely stated that in no direction has the use of electricity in mines made more progress during the last three years.

The advances made in mining switchgear have been principally in the direction of ironclad designs, in which the whole of the protective apparatus is enclosed. The article by Mr. H. W. CLOTHIER, and also the descriptions of the apparatus made by the principal manufacturers supply an accurate record of the work done. The liquid controller and oil-immersed resistance have come more prominently to the front and merit the special attention of mining electrical engineers. The development of gate-end protective systems is also a good sign of progress. If the confidence of the men in these methods can be obtained a great deal will have been done to remove the existing prejudice of miners to the use of electrical apparatus at the coal face, for it is at this particular point that the men take exception to the employment of electrical plant. The practical operation of these protective systems should be closely followed during the next year or two. Mr. CLOTHIER draws particular attention to one of the weak points in switchgear, that at which the cables are led into the switch equipment. Great care is now being taken to provide special protection at this point. Leakage is particularly annoying on ordinary aboveground installations; in mines it becomes dangerous also. Mr. CLOTHIER shows how various protective systems which are now used exclusively aboveground can be modified to suit underground requirements.

Besides designing the switchgear so that it shall be capable of safe employment in mines, modifications must be introduced into the design of motors, especially those driving coal-cutters and similar plant in explosive areas. Mr. TALBOT DUCKITT advocates consideration of the design of motors which have been introduced to fulfil these conditions.

Mr. A. B. MALLINSON contributes an interesting article in which he discusses various points to which attention must be given in colliery wiring. The cable in process of erection is rather a tender plant, and great care must be taken how it is handled and fixed if it is not to give trouble afterwards.

Great progress has also been made in the electrical operation of coal-cutters. Here again the opposition of the miners themselves is serious. The conditions under which the motor has to operate, and the work it has to do, are by no means ideal, and much experimenting has had to be carried out before a suitable machine has at last been placed on the market. Mr. H. J. FISHER, in his article, deals also with the proper connection of this apparatus to the mains. The trailing cable comes in for hard usage; and an interesting method of getting over this difficulty is to enclose it in rubber of a quality similar to that used on pneumatic tyres.

Mr. W. MAURICE'S article shows that progress is also being made in the use of electric lamps in mines. The aggregate number of the lamps may be small at present compared with those of the oil type, and there is yet much to be done in this direction. There is no doubt that from every point of view this type of lamp should receive the consideration of all mine-owners.

In conclusion we may draw attention to the two articles by Mr. NEIL TAYLOR and Mr. C. F. MACKNESS respectively. Mr. TAYLOR deals with the present position of the electric drive in Cornish mines. These mines are, as is well known, amongst the oldest existing in this country, and it is found that electrical equipment for their operation is no less useful here than elsewhere. An interesting development illustrated in this article is the use of the Diesel engine as the prime mover in the power house. Cornwall, not having coal among its natural resources, provides a fitting field for this type of plant. Mr. MACKNESS deals with the great progress that is being made in the use of electrical apparatus in South African mines, where, as mentioned above, the conditions are considerably different from those existing in this country.

Besides these signed articles from the pens of men of large and varied experience, a number of descriptions of mining installations, and of equipment suitable for mining work, which have been supplied for the purpose by the leading makers, have been included, and we hope THE ELECTRICIAN SECOND MINING ISSUE will be found to be an accurate guide to the actual state of affairs in a department of electrical enterprise where development of this kind makes for the improvement of the working conditions of a most important branch of industry.

Electricity in Cornish Mines.

BY NEIL TAYLOR.

Summary.—An account is given of the very special conditions existing in the metalliferous mines of Cornwall, and of the points to which particular attention must be given. Stress is laid on the importance of securing good results in pumping. Owing to the extreme conservatism of those connected with this isolated branch of mining there has been considerable difficulty in introducing electric plant, but much headway is now being made.

It is only a few years since electricity was introduced into Cornwall for the various requirements of metalliferous mining, and its progress has been comparatively slow. The older concerns have been a long time in realising its usefulness for their particular purpose. Fortunately for progress, the newcomers, or foreigners as they are locally termed (*i.e.*, anyone who hails from the other side of the Tamar), are determined to instal the most modern equipment with a view to economy.

Practically all new ventures which have been recently started in the county have contented themselves with reopening abandoned mines. Naturally, the first and most difficult problem to be faced is the unwatering of the mine. In most cases this has been a difficult proposition owing to the scarcity of reliable information and the trouble due to the shafts themselves. Old plans are of little service and cannot be depended upon. The difference in the amount of incoming water in summer and winter is very considerable, so that great care requires to be exercised in the choice of pumping plant.

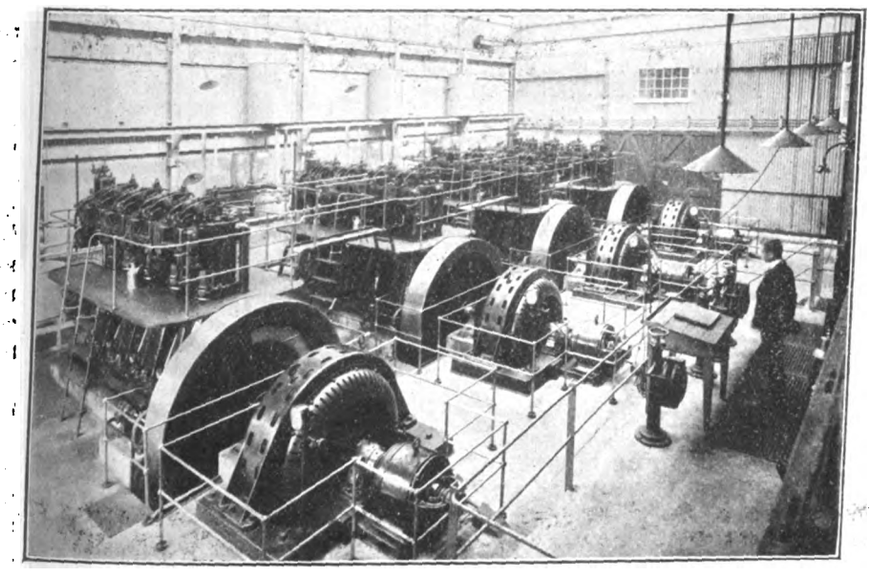

FIG. 1.—INTERIOR VIEW OF A MINE POWER STATION, HAVING FOUR SETS OF ENGINES AND ALTERNATORS, EACH SET OF 200 B.H.P. DIESEL ENGINE DIRECT COUPLED TO A 135 KW. ALTERNATOR, 650 VOLTS, 50~, THREE-PHASE WITH EXCITER.

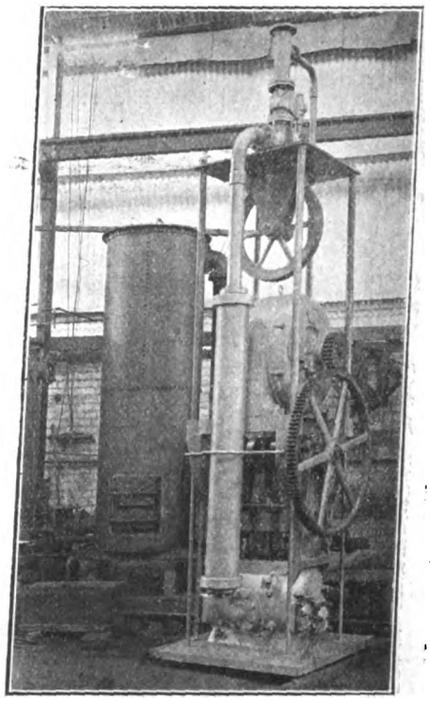

FIG. 2.—500 FT. HEAD THREE-THROW ELECTRIC SINKING PUMP, 250 GALLONS PER MINUTE.

As a rule there is no scarcity of shafts, but what they make od in numbers is entirely negatived by their size, or rather ınt of size. Shafts are rarely perpendicular for any depth d take all sorts of angles in their downward course. After ciding on the shaft which will be most suitable for pumping erations, the next point, and probably the most important, is fix on the most suitable type of pump under the adverse ıditions obtaining.

There are three schools of thought on this thorny question of proper system to be adopted for the unwatering of Cornish ies. First, the old school who know of only one pump, a nish pump, and only one prime mover, "a Cornish beam ine," and only one boiler fit to supply steam for the engine, Cornish boiler." After which we come to the so-called modern slap-up-to-date set, who maintain, with equal tenacity to first set, that electrical pumping is the only system. The term electrical pumping, at this end of the world, has become known as a combination of a high-speed motor and a turbine type of pump. Then follows the third set, who endeavour to treat each proposition on its merits and decide in accordance.

To obtain a clearer view of this knotty problem let us look at some of the difficulties :—

1. Mine full of water.
2. Incomplete data regarding coming water.
3. No data as to amount of water in the mine.
4. No reliable information as to size or inclination of shafts.
5. Chocks in shafts.
6. Acidity of water in many cases.

The chief argument used in favour of the Cornish pump is its reliability, but within recent years quite a few engines have come to grief with broken bobs, and where this has occurred considerable time has been lost in replacing the broken part. Another trouble with the Cornish pump is broken pump rods; also where shafts are small, the space taken up by rods and gear is a great disadvantage.

Electrically driven turbine pumps are found to be troublesome in upkeep, and as a rule are difficult of access for repair. Wear and tear is greater in this class of pump than with a Cornish pump, but when discussing unwatering propositions it must be borne in mind that the real object is to get at the producing stage as quickly as possible, so that although the turbine pump is more expensive in upkeep it generally gets there in quicker time.

The ordinary ram pump has probably done better work in unwatering than any other; it has the great advantage of

simplicity in construction, and is less costly in maintenance. But the pump which has proved to be the best is a two or three-throw ram pump using Guttermuth valves; it is less liable to break down, is simply designed and better suited to the conditions. Not all mines are troubled with acid water, but a great many are, and notwithstanding that this is known, materials are sometimes used in construction which can only cause trouble and annoyance.

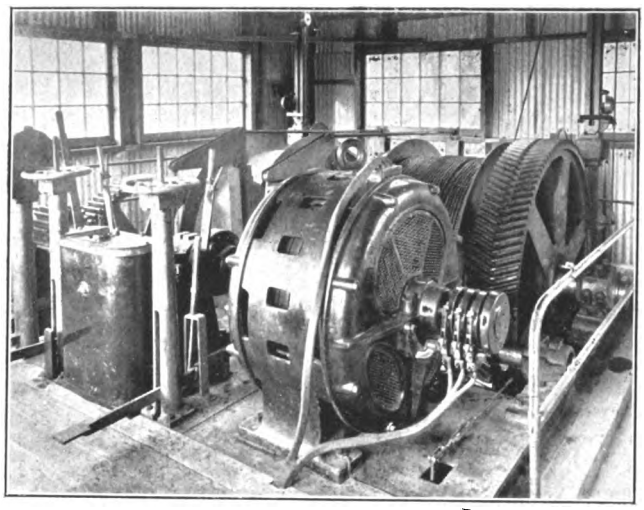

FIG. 3.—120 B.H.P. DOUBLE-DRUM ELECTRIC WINDER WITH NO-VOLTAGE BRAKE MAGNET AND OVERWINDING DEVICE.

Coming to the matter of cost, the installation required for a steam Cornish pump is much heavier in first cost than that required for electrical pumps of any type. The steam Cornish pump is mentioned because a few Cornish pumps have been electrically driven, and where the rods are properly balanced there is no difficulty in using electricity as the motive power; but at the same time it may be mentioned that there is no great saving by so doing, as efficiency is lost in the intervening gearing to reduce the speed down to the 5 to 8 strokes per minute.

To obtain a fair comparison of costs is a matter of some difficulty, but where electricity is generated on the mine and used for other purposes, or can be bought in bulk supply at a reasonable price, then there is no doubt but that the balance is very much in favour of electricity as a motive power for pumping. It is immaterial whether a pump is driven by steam or electricity, the pump will still absorb power, but the electric motor is usually more efficient than a steam pumping engine. The greatest point in favour of the use of electricity is its flexibility, and it scores heavily over steam in this respect.

Mistakes have been made in pumping schemes, but this is not to be wondered at when all the factors in the equation are practically unknown. In addition to these natural difficulties, there is a very strong prejudice against the use of electricity, and this does not tend to make for successful results. In time these prejudices will be worn down, and we may look for much better results.

Coming to the question of station pumps, the problem is a very much simpler one, and in this case there is no question as to the great superiority of the electric ram pump over the Cornish. The space occupied is much smaller, and in the shaft itself the rising main and a small cable represent the sum total of the space, whereas the Cornish pump has a great rod in addition to the rising main, and the space taken up by the poles is quite considerable; all this in a shaft, where the space is already much too small. Again, the pumping engine takes up valuable space around the shaft which could be used to much greater advantage. When long rods have to be used in deep shafts the Cornish pump becomes very troublesome and expensive owing to the rods breaking.

Where trouble is likely to arise with electrical pumping plants is generally due to the following causes. The chief consideration must be given to reliability, even before efficiency, although with careful design it is possible to obtain both. On the electrical side the most fruitful source of trouble is found in the starter. Unfortunately makers seem to think that they are all right if they turn out a good motor, and that the starter is of secondary importance; but in this as in all cases the strength of the combination of starter, motor and pump is the strength of its weakest part, and in most cases the starter is the weakest part.

As in all apparatus for underground use—chiefly abuse—attention must be paid to mechanical strength; it therefore behoves makers to put more brains into the starters for underground switchgear. Connections are not massive enough, and as a rule there are still too many screws which require the use of watchmakers' tools instead of an engineer's spanner. Distinct stops, such as one can feel, are an absolute necessity, as it is not possible to see the fine markings usually supplied; they may serve in the laboratory but are worse than useless in the mine. Connecting boxes are also much too delicate and screws are so fine a pitch that after a screw has been out once or twice the thread is spoiled and valuable time is lost re-tapping.

With motors there is a tendency to work with very fine air gaps; this, for mining plant, is simply courting disaster. In every enclosed type motor provision should be made, by fitted plugs or other means, for the insertion of feelers at three equidistant points in the circumference of the casing opposite the periphery of the rotor so, that examination can be made as to the condition of the air gap; by so doing, proper inspection can be made and much trouble and loss of time can be saved.

If makers would arrange for their designers to study conditions on the mine they would then be in a position to supply suitable plant for the severe conditions. Everything should be as simple as it is possible to make it and all useless frillings should be avoided. In the pump itself the valves should be easy of access and readily removable: it should be arranged that plungers can be taken out without dismantling three parts

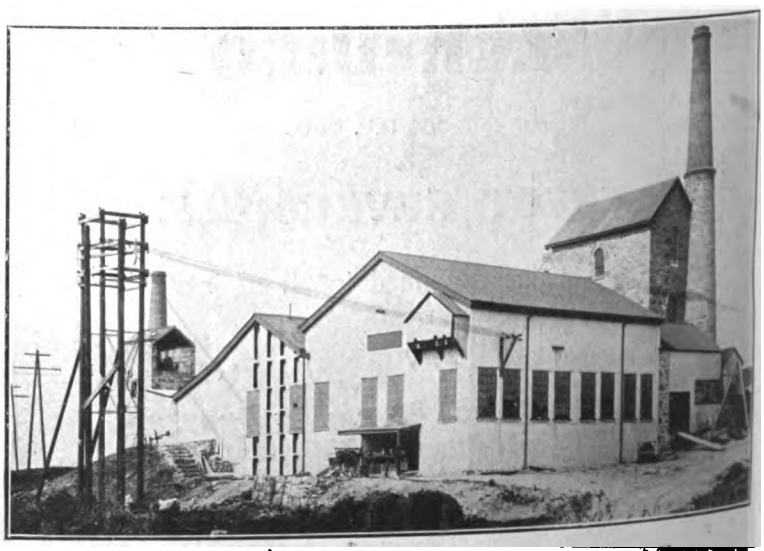

FIG. 4.—VIEW SHOWING 6,000-VOLT TRANSMISSION LINE ON A-

of the pump and electrical gear. All brasses should be easily accessible, and ought to be interchangeable.

Speaking generally, under the conditions obtaining in the county and after considerable experience in all classes of sinking pumps, the most suitable for the unwatering of Cornish mines appears to be a two- or three-throw ram pump driven through

gearing by a squirrel-cage motor, and having a very substantial starter. Such a set is shown in Fig. 2.

Simultaneous with pumping operations it is usual to instal a hoist, so that timber and other material can be raised and lowered as required. Owing to the size of the shafts and to the irregular twists in them, fast winding is impossible. Fortunately, when a mine reaches the producing stage the amount of ore it sends to the mill is comparatively small, and the slow winding does not cause serious inconvenience. Figs. 3 and 6 show electrically-driven hoist and winders, such as are used in Cornish mines.

Owing to so few of the shafts being vertical, few cages are used, self-dumping skips being more in evidence. In the majority of cases single skips are used, not of choice but of necessity, as very few of the shafts are large enough to permit double skips in addition to the other gear. The amount of ore hoisted is small; therefore small-powered hoists are in common use, 100 to 150 B.H.P. being a fair average. Depths vary from 480 to 3,000 feet. Amongst the newer concerns electrical winding gears are favoured, being more reliable and easier to control; also they can be more readily fitted with real safety devices than can steam hoists.

Air compressors are used for the supply of air for rock drills, are mostly steam-driven and situated on surface. A few electrically-driven compressors have been installed on some of the mines and are giving satisfaction, but so long as compressors are erected on the surface a long distance from the

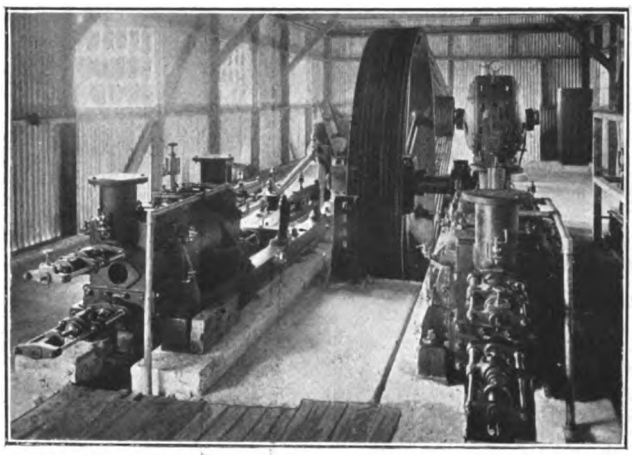

FIG. 5.—105 B.H.P. ELECTRICALLY-DRIVEN AIR COMPRESSOR.

point of use the overall efficiency will continue to be low, and even a few per cent. loss in efficiency in a machine which runs 24 hours a day represents a very considerable amount in 12 months' working. Probably, when makers realise the large field before them, they will endeavour to place a machine on the market to comply with the conditions. A sound, strong and reliable electrically-driven compressor which can be run close up to an end or stop, capable of driving three 3 in. rock drills, would form an efficient combination, and would soon pay its first cost. An electrically-driven compressor is shown in Fig. 5.

Rock drills are worked by air and the exhaust forms the only means of ventilation in such cases. The first cost of a drill is not a very heavy item, but the repair bill is very heavy, and the efficiency is low. When some ingenious inventor comes along with a simple and strong electric drill, he will find a very large field ready for exploitation. The saving in first cost of air plant would be considerable, and its flexibility would be a strong point in its favour, whilst the overall efficiency would be a long way ahead of the air-driven machine with its cumbrous pipes and expensive surface equipment.

Signalling is usually accomplished by means of a wire rope and a mechanical bell, which is not so efficient or simple as electrical signalling. With the electrical signal a more definite signal is given, and, most important of all, there is not the same liability of error.

Shot firing by electricity is practically an unknown quantity so far, but doubtless as the use of electricity becomes better known advantage will be taken of this power for this purpose.

Of underground lighting there is none, except where energy is used for pumping; then a few lights are fixed around the pumps, and in a few cases at the more important levels around the shaft. Beyond this there is little possibility of extending the lighting system, as the levels are very small.

Hauling the ore from the stopes is effected by man-power trams, and in the smaller levels by wheelbarrow. There is

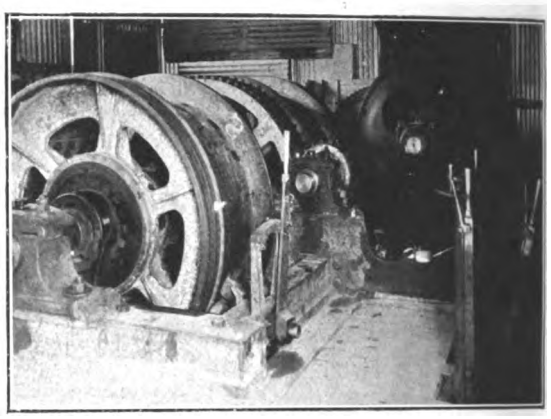

FIG. 6.—100 B.H.P. DOUBLE-DRUM ELECTRIC HOIST WITH LIQUID CONTROL.

little doubt that where electrical energy is available small in-bye haulage gears would prove of great service, and be more efficient and less costly than the systems at present in use.

Natural ventilation is depended upon, but in many of the deeper mines, where the temperature is fairly high, small auxiliary electric fans would be of great assistance in giving a good supply of fresh air. By installing small auxiliary fans throughout the workings more work could be done by the miners, with less fatigue, and would tend to a higher efficiency all round.

When the ore reaches the surface it is taken to the rock breaking station where it usually passes over a grizzley, to rid it of the fines, the over size passing through a coarse rock breaker, then over a second grizzley, the over size again passing to a second stage breaker the material falling into a bin. The position of the rock breaking station depends on local conditions, but where there are a number of shafts hauling ore it is cheaper in first cost and in running charges when this plant is centralised.

FIG. 7.—ELECTRICALLY-DRIVEN VANNER.

Coming to the mill, the ore is deposited in bins immediately behind the stamps and automatically fed into the mortar boxes. The old method of driving the stamps was by a beam engine, and a few examples of this method are still in existence, but the latest practice is to drive by electric motors (by belt). From the stamps the pulp passes through classifiers on to

Digitized by Google

vanners, slimers, round frames, &c. In many cases where the vanner gives a middle product this is treated in a pulveriser; but the arrangement and class of table used depends on the ore to be treated.

For final treatment the concentrate is generally passed through a calciner which has a very slow movement, sometimes 1 rev. in 25 minutes. Then there are more tables, frames and buddles before the required degree of concentration is reached, and the black tin is ready for the ticketing.

For some ores a magnetic separator (Fig. 8) is used with great advantage; for example, in separating tin, wolfram and iron. This machine has been of great benefit to the mines, as it not only enables them to get a much higher price for their tin, but it also increases their income by the sale of valuable bye-products.

A strong point in favour of electrical driving of vanners, tables, and other concentrating machinery is the steady drive obtained, no such uniformity can be obtained by a steam drive. It is most important that all concentrating machinery should have an even turning moment. Fig. 7 shows a typical machine of this kind.

In the early stages of the use of electricity in Cornish mining, it was a matter of some difficulty to estimate the horse power required for the several machines to be driven, as users had a very hazy idea as to how much power was required for the plant. Later, however, when electricity came into more general use, it was a simple matter to find what power was required for driving the different machines on the mine. At the same time,

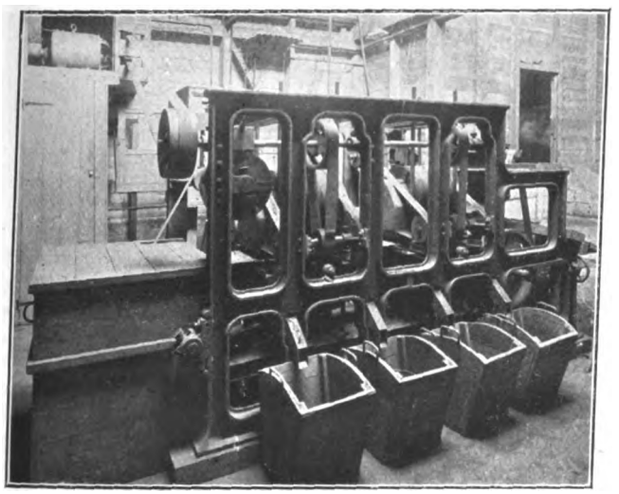

FIG. 8.—MAGNETIC SEPARATOR, ELECTRICALLY-DRIVEN, SEPARATING TIN, WOLFRAM AND IRON.

by keeping an eye on the various measuring instruments, one could tell exactly as to the efficiency of each piece of machinery under observation. Not only so, but the individuals whose duty it is to look after these machines take a much keener interest in their proper maintenance, as they can see exactly what power is being taken under varying conditions, the net result of this being, where electricity is the motive power, that not only the motors but the driven machines are kept in a very much higher state of cleanliness and efficiency than where steam-driven plant is installed.

The majority of the mines using electricity have their own power stations, but a power company is now in the field, and it will depend entirely on the rates offered whether it will pay the mines to buy in bulk or continue to generate their own electrical energy. Amongst the mines there is only one now in use (as far as the writer is aware) where steam drives the prime mover in the power station; several have gas-driven stations and one has Diesel engines using crude oil as fuel. Where the mines have their own power station three-phase alternating-current at 50 periods is the usual custom, and for general mining conditions this arrangement seems to be the most suitable. A Diesel station is illustrated in Fig. 1, while a typical overhead line is shown in Fig. 4.

The amount of power required varies according to the size of the mine, but the following will give a rough idea of the general requirements. Pumps vary in capacity from 150 to 750 gallons per minute; of course there are exceptions, some smaller and some larger. During the unwatering stage, pumping is a very expensive item, as not only has the coming water to be dealt with, but the pool has to be attacked. The actual time taken to unwater is not great as a rule, but delays occurring due to chokages and making the shaft good so that a good deal of time is often spent in one position where these hindrances are met with. Winding engines take about 100 to 150 B.H.P., whilst air compressors take about 100 B.H.P. It must be clearly understood that the figures given are fair average. Where the surface is lit by electricity, about 220 16 c.p. lamps may be taken per mine, and, naturally, where this method of illumination is used a better light is expected than where oil lamps and candles are in vogue.

Coming to rock breakers it has been found that they take about 13 B.H.P., although the starting current is rather high. Experience shows that course and fine rock breakers take about the same power. Californian stamps are more used than any other type, and the usual practice is to drive each 10-head by a separate motor. For a 10-head battery of 1,050 lbs. per head, a 30 H.P. motor is a good size to instal, the average power taken being about 22 B.H.P. A 6 ft. by 2 ft. pulverizer takes about 4 B.H.P., while vanners, slimers, tables and round frames absorb just under half a horse-power each, inclusive of line shafting. Tube mills absorb about 10 B.H.P.

Electrically-driven Belt Conveyors.

Some details of a conveyor plant which is installed at an American gold mine for bringing up the ore to the crushers are given in a recent issue of the "Engineering and Mining Journal." On two of the conveyors a Scandinavian belt was first used. These belts lasted about 18 months. They were replaced by the best grade rubber belts, which are troughed and are about 30 in. wide. Each of the belt conveyors takes the ore up a slight incline and then feeds it to a grizzly having bars 7 ft. long spaced to give 1½ in. openings and set at an angle of 30 deg. The oversized pieces from each grizzly go to a gyratory crusher. The undersized pieces from these grizzlies, after being rejoined by the crushed oversize, is either taken by conveyor or passed by chutes to two trommels, 12 ft. long and having a diameter of 2½ ft., on which a cast-iron screen ½ in. thick and having holes ½ in. in diameter is used. Each trommel feeds its oversized pieces to a gyratory crusher, which breaks the ore to 1½ in. size. This re-crushed ore then rejoins the undersize from the trommels and is taken by two Stevens-Adamson belt conveyors, 18 in. wide, up an angle of 20 deg. to one of two distributing belts, also 18 in. wide. Each of these serves half of the fine-ore bin. These distributing belts are dumped by travelling trippers that discharge the ore over the end of the belt, and in this manner an even character is assured to the ore throughout the fine bin. The fine-ore bin, which has sheet-steel sides, and, like the coarse-ore bin, is made with a flat bottom, is 580 ft. long, 22 ft. wide and 20 ft. deep, so that it holds about 16,000 tons when filled. It is in the mill building proper between the two rows of Nissen stamps, which were originally installed. In fact, the bin structure formed part of the frame for the stamps. Oversized crushers and the automatic feeders, as well as the two coarse-ore conveyors, are driven by a 150 H.P. motor, while the two gyratory crushers and the trommels are driven by a 75 H.P. motor. The two belt conveyors are driven by a 30 H.P. motor, while each of the distributing belts at the fine-ore bin is driven by a 20 H.P. motor. All of these motors are of the Westinghouse induction type, as are the other motors throughout the mill. They all operate at 440 volts on a three-phase circuit with a frequency of 20.

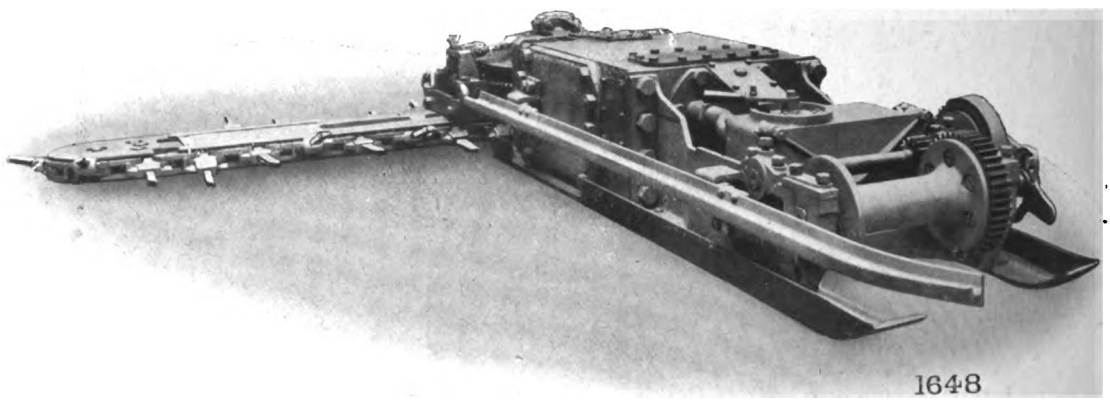
Chain Coal-Cutter.

ERNEST SCOTT & MOUNTAIN, Ltd.,

GATESHEAD-ON-TYNE.



The type of Coal-Cutter illustrated above has been specially designed by us at the request of several colliery friends, with a view to overcoming several of the objections of both the Disc and Bar types of Coal-Cutter.

From the experience which we have gained in the past with Disc machines, and later with the present type of Chain machine, we are satisfied that it is possible to work a Chain type of Coal-Cutter under the most severe conditions with complete satisfaction, and in positions where we are very doubtful if any other type of machine can be satisfactorily employed.

This type of machine has been very carefully designed, and the following points are particularly of interest :—

The whole **framework** is of **cast steel,** and of great strength.

The **motor** and all the **electrical gear** is **flame-tight** and **water-tight.**

The jib is arranged to **cut both in and out of the coal automatically,** and can be slued through 180 degrees.

The **motor** is **very amply rated,** and is of special construction to withstand the vibration. It is provided with a **large number** of **inspection doors,** and can be easily dismantled.

The sides of the motor casing carry the poles with their windings, and can be removed when required without dismantling the cutter.

The full illustrated description of this type of machine will be sent on application to

The Position of Electricity in Mining in South Africa.

BY C. F. MACKNESS.

Summary.—An account is given of the enormous progress made in the application of electricity to mining in South Africa. This is particularly noticeable in electric winding, the progress of which has quite eclipsed anything in this direction in Europe. Brief particulars are given of the public power supply systems, which have received an impetus through the advent of the Victoria Falls & Transvaal Power Co. The minor applications of electric power are also described, including locomotives, haulages, stamp and tube mills, pumps and other uses.

The continuous progress that is being made in Europe in the use of electricity in new fields hitherto untouched, keeps the attention of engineers who are interested in such developments mainly directed to what is being done in Europe, and it is probably not too much to say that few engineers in this country are conversant with the progress that is being made in our Colonies in the applications of electricity.

As most of the electrical machinery which is sent to our Colonies is manufactured in Europe, there is a natural tendency on this side to look upon Europe as being in the van of progress in electrical work, and to think of the Colonies as following our lead.

Whilst this may be generally true, the following brief account of what is now being done in South Africa will show that the engineers there are not only fully conversant with all the developments in this country and in Europe, but that they also have the courage to act up to their convictions, in making themselves responsible for the installation of electricity in the mines for power purposes, to the exclusion of every other form of power, and on a larger scale than has yet been contemplated either in Great Britain or on the Continent, or elsewhere.

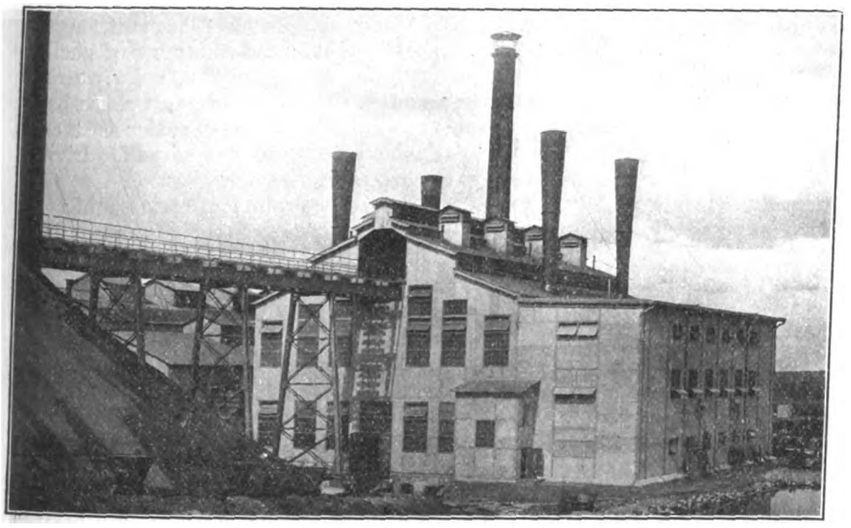

FIG. 1.—SIMMERPAN POWER STATION.

Specifications are straightforward, concise, and clear, showing that the engineers know what they want and why they want it, and the installations now being completed prove those responsible for the work to be as capable and clever a set of engineers as can be found anywhere.

General.—It can now be safely stated that steam power has practically been abandoned by the mining groups as a motive power in favour of electrical power, either generated by one or more central electric power stations supplying all the mines belonging to one group, or obtained from the Victoria Falls & Transvaal Power Co.'s mains. The smaller and isolated mines, whose requirements are small, have their machinery still driven either entirely by steam engines, or only partly by electrical power, but the bulk of the mines are now dependent entirely upon electricity for the running of all their machinery.

The use of continuous current may also now be considered as exceptional, the larger power stations supplying three-phase alternating current at high pressure, and at a frequency of 50 or 25 cycles.

Continuous current is only used on some of the smaller mines or for special purposes, such as supplying electric locomotives, &c., on the larger mines.

Power Stations.—The largest power stations on the Rand are naturally those belonging to the Victoria Falls & Transvaal Power Co. This Company has now three power stations in operation, the total capacity of which will be 175,000 H.P. when working to their full ultimate capacity.

Space does not permit of any detailed descriptions of these stations being given here, but an outline of the general arrangement of the stations and the distribution scheme may be interesting.

Three of the four power stations are now in operation, these stations being situated along the reef from east to west at Brakpan, Simmerpan and Rosherville. A fourth power station is to be erected at Vereeniging, which is some 35 miles from Johannesburg. The Brakpan power station is the smallest of the three and contains two turbo-alternator sets each of 3,000 kw. output. The Simmerpan station (Figs. 1 and 5) is at present equipped with four turbo-alternator each of 3,000 kw., but the ultimate capacity of the station will be 24,000 kw.

The third power station, at Rosherville, (Fig. 2) is not yet completed, but will be the largest of all. The generating plant will consist of five turbo-generator sets each of 12,000 kw., these sets being the largest units at present in operation. A general view of this station is given in Fig. 3. In addition to supplying electrical energy this station will also supply compressed air in bulk, for distribution to the mines belonging to the Eckstein group. The compressed air plant consists of four steam turbine-driven turbo-air-compressors, each of 4,000 to 5,000 H.P. This power station is interesting, therefore, as containing the largest turbo-generator units, and in addition to this, the largest air-compressors yet built. The Robinson Central Deep compressor station is shown in Fig. 4.

All these stations are laid out on the most modern lines, and they contain a number of interesting details conducive to economy in running and efficiency. The boilers, economiser and chimneys are arranged in units, a separate short steel chimney being provided for each pair of boilers. Induced draught is used throughout, each of the above-mentioned units having its own separate induced draught fan. The system used is novel, the principle employed being that of the ejector, so that the fan deals only with cold air, which is forced into the chimney and creates the suction for the flue gases. The boiler efficiency attained with this arrangement of the plant is excellent, in spite of the fuel used being of only indifferent quality. Chain grate stokers are used, and the coal and ash conveying arrangements are carefully designed for efficient and economical operation.

The switchgear is arranged for remote control, the high-tension switchgear and 'bus-bars being sub-divided and

Digitized by Google

sectionalised as usual in modern power stations, and built into fireproof cells.

In these power stations one of the most unusual features, to engineers who are accustomed to British conditions, is the lightning arresting equipment. As the major portion of the transmission and distribution network consists of overhead conductors, it is essential that special care be devoted to the avoidance of all risk of disturbances of supply, due to the direct or indirect effects of thunderstorms, which are severe and frequent on the Rand at certain times of the year. Hence

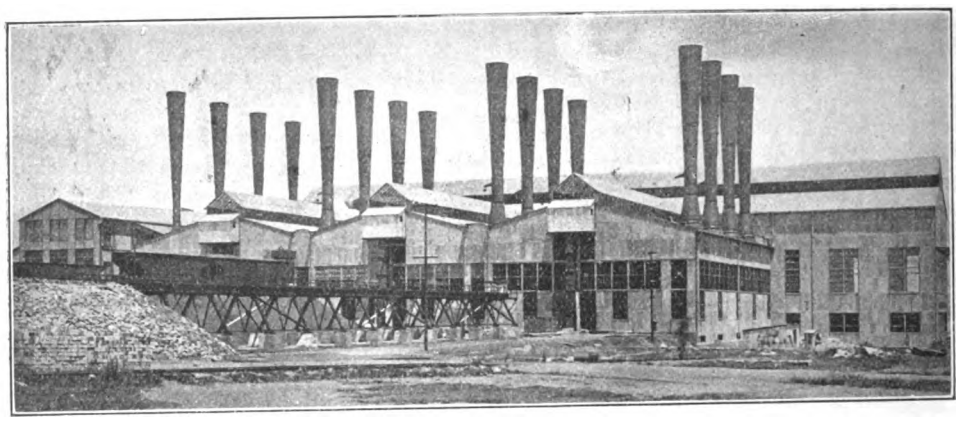

FIG. 2.—GENERAL VIEW OF ROSHERVILLE POWER STATION.

the expensive equipment of choking coils, spark-gaps, fuses and electrolytic and horn-type lightning arresters, which are unnecessary in Great Britain, is indispensable for these power stations on the Rand, where any interruption of supply means the complete stoppage of all the mines supplied by the section affected.

The Brakpan power station supplies the mines at the eastern end of the Rand through overhead lines at 10,000 volts. There is a transmission line at 40,000 volts extending along the whole length of the Rand, and in addition to this a cable distribution system is laid in the central part of the Rand, which is supplied partly from the Rosherville power station and partly from the Robinson Deep sub-station.

The energy is distributed to sub-stations at the various mines, where it is transformed to 2,000 volts or 500 volts to suit the mine requirements. There are in all some 32 sub-stations, having a capacity of 1,000 to 6,000 kw. each. At the Robinson Deep mine a main sub-station is placed, and this station is also equipped as a compressed air supply station. There are six turbo-air-compressors installed, each of 4,000 to 5,000 H.P., and these are driven by direct-coupled synchronous motors. The distance between the stations at Brakpan and Simmerpan is 15 miles, and between the latter and Rosherville about 7 miles. The sub-station at Robinson Deep is 12 miles from the Rosherville power station. The combined output from the power stations of the Victoria Falls & Transvaal Power Co. is expected to reach four hundred million kilowatt-hours per annum in the very near future.

The above will show that the formation of this Company has been amply justified, and it is quite clear that those who control the mining groups share the opinions held by their engineers as to the advantages to be gained by the mines from a cheap and reliable supply of energy in bulk, such as the Victoria Falls & Transvaal Power Co. is able to offer. There is every prospect of the working costs of the mines being reduced to the figures estimated by the engineers, when the equipments of the mines are completed and in operation.

Apart from the power stations belonging to the Victoria Falls & Transvaal Power Co., there are several large power stations built by mining groups to generate the energy required by their various mines. Of these power stations some were in existence before the bulk supply scheme was mooted, whilst others have been built on the advice of the engineers responsible to the mining groups concerned, and in the belief that such private power stations of the capacity in question (say, 6,000-20,000 kw. can give a supply of energy at lower rates than any bulk supply company can offer.

Of these stations that of the Randfontein Estates group is the largest, the plant installed aggregating 20,000 kw. in modern steam turbo-alternators. The supply is three-phase at 6,600 volts, 50 cycles, energy being transmitted by cables laid underground to a number of sub-stations in which static transformers are installed. The power station is designed and built on the most modern lines, and contains all the appliances and apparatus necessary to ensure continuity of supply and economy in running costs. The cable system is duplicated throughout, and is protected against risk of interruption by means of Merz-Price protective apparatus.

Next in point of size is the power station of the East Rand Proprietary Mines, which will ultimately be nearly as large as the Randfontein Estates power station. Three-phase current is supplied from this station at 3,000 volts, and at a frequency of 25 cycles. The plant consists of a 6,000 kw. steam turbo-alternator, and a number of smaller steam engine-alternator units. A second 6,000 kw. turbo-alternator set will be installed shortly. This station has been in operation for some years, but is being modernised and enlarged to cope with the increased output required for driving the winding engines, pumps, and other new plant.

Another power station is nearing completion, to supply the New Kleinfontein Mines (Farrar Anglo-French group). This station also supplies three-phase current at a frequency of 25 cycles. The plant consists of turbo-alternator units totalling 6,000 kw. at present. Energy is transmitted from this station to the various mines belonging to this group. Some of the mines are equipped with continuous-current motors, and motor-generator sets are being installed to convert the three-phase supply to continuous-current for supplying these motors. The township of Benoni will also be supplied with energy for lighting purposes from this station.

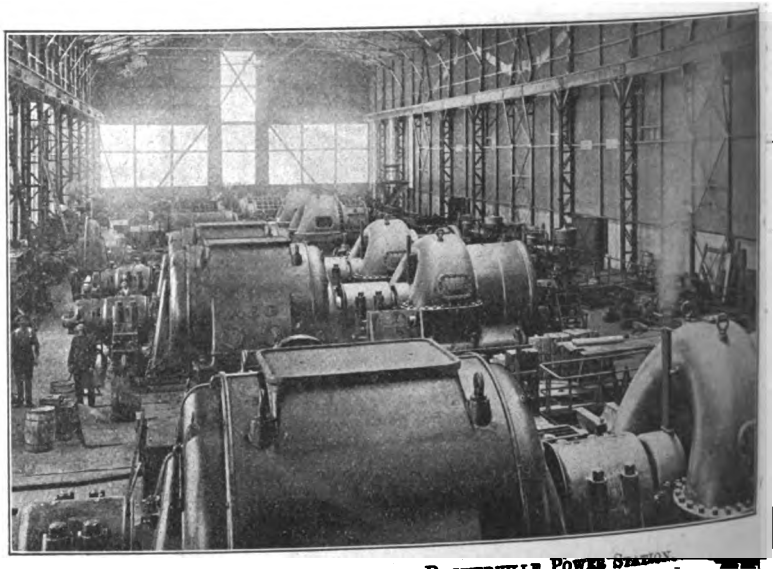

FIG. 3.—ENGINE ROOM AT ROSHERVILLE POWER [illegible]

There is confliction of opinion on the question of frequency,

Digitized by Google

the two last mentioned groups having adopted 25 cycles, whilst the other stations have chosen 50 cycles. The higher frequency was also adopted by the Victoria Falls & Transvaal Power Co. for all their stations after very careful consideration.

The only apparent advantages of using 25 cycles are :—

1. Motors of usual outputs and speeds have a slightly better efficiency and power-factor (about 1 per cent. average).

2. Where large slow-speed motors are used the power-actor and efficiency are considerably higher than those of 50 cycle motors for the same conditions.

This affects such cases as the driving of air compressors and stamp mills by direct-coupled motors, and also is important in the case of winding engines driven by large slow-speed motors direct coupled to the drum shafts.

The chief disadvantages of the lower frequency are :—

1. The plant costs more.

2. The possible motor speeds are more limited.

3. The speed of 3,000 revs. per min. is lost, which may prevent the use of centrifugal pumps and motor-driven turbo-air-compressors.

4. 25-cycle plant not being standardised, more spare parts have to be kept, and everything required must be specially ordered.

In addition to the above, should a favourable offer be made by the power company for a bulk supply, the consumer has to suffer the conversion losses in the frequency-changers which must be installed to convert the supply from 50 cycles to 25 cycles, and which must be installed by the consumer at his own expense. Taking everything into consideration, therefore, the frequency of 50 cycles appears to be quite suitable for mining work, and its advantages outweigh those claimed for the lower frequency by its advocates.

Distribution.—In earlier days, distribution on the mines was usually effected by means of overhead wires. The tendency now, however, is to use underground cables, thus avoiding all risk of interruptions from atmospheric disturbances. The overhead mains used by the Victoria Falls & Transvaal Power Co. are unavoidable to a great extent, as cables are not yet reliable at 40,000 volts pressure, as used for the main transmission lines of this Company.

A distribution cable network at 20,000 volts is used for the central portion of the area served by the Company, as already mentioned. The overhead lines are protected by earthed guard wires run above the conductors, in addition to the lightning arrester equipments which are installed in the power stations and sub-stations. Both the cables and the overhead lines are protected on the Merz-Price protective system, to lessen the risk of interruption of supply, and the transmission and distribution systems have been carefully laid out so that, wherever possible, there are duplicate feeders to each consumer, or group of consumers. On the mines themselves, that is to say, on the consumers' distribution sytems, underground cables are now usually laid, the extra first cost being considered as a cheap form of insurance against risk of interruption of the supply.

Sub-stations.—The sub-stations are built by the mines to the designs of the power company, at least as far as concerns the high-tension side. The buildings are practically divided into two parts, the high-tension part containing the incoming feeders, lightning arrester equipment, isolating switches, 'busbars and step-down transformers, all of which are provided by the supply company. The low-tension (2,000 or 500 volt) side is usually arranged by the mine engineers to suit their requirements. The high-tension switchgear and 'busbars, &c., are arranged in fireproof cells, as is now usual.

The energy is metered to the consumers on the low-tension side of the step-down transformers, from which leads are taken out to the main low-tension distribution switchboard 'bus bars through the partition wall. The sub-stations are usually built of brick, and the arrangement of the apparatus and switchgear is equal to the best that can be seen in Europe. The sub-stations underground also compare very favourably with the best practice in this country. The switchgear is well arranged, and accessible, and the chambers are roomy, clean and well kept.

Applications of Electricity on the Mines.—The current is used above and also underground. The main purposes for which current is used are :—

Above Ground.—

For the main winding engines.
Driving air compressors.
Electric locomotives.
Haulages.
Conveyors.
Stamp mills.
Tube mills.
Crushers.
Pumps.
Shaking tables.
Also for driving a number of small-power machines used for various purposes in the treatment of the ore.

Underground.—

The principal uses found for electricity below ground are :—
For driving electric winding engines for hauling ore on the incline of the reef.
For operating pumps.
For lighting.

Of the above applications, by far the most important is that of the substitution of electricity in place of steam for driving the winding engines.

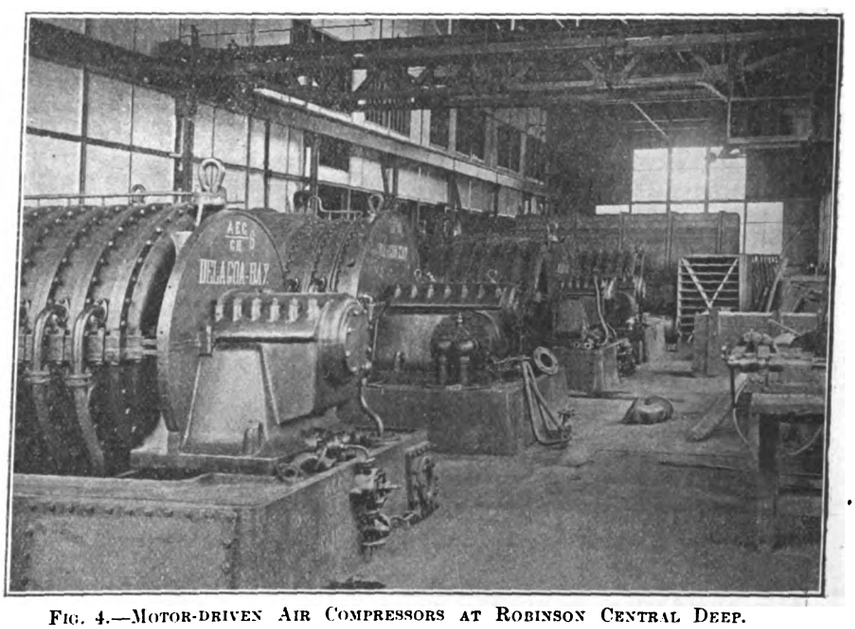

FIG. 4.—MOTOR-DRIVEN AIR COMPRESSORS AT ROBINSON CENTRAL DEEP.

The wholesale manner in which these electrically-driven winding engines are being used on the Rand has no parallel in Europe or elsewhere, either in the number of the installations or in the sizes of the motors employed. When the electrical winding engines now being installed on the Rand goldfields are in operation they will form a huge practical exhibition of this application of electricity that can only be looked upon as astonishing, when compared with the slow adoption of the electrically-driven winding engine in Europe, where it had its origin ; and this is further testimony to the enterprise and courage of the engineers responsible for the wholesale adoption of electricity for this important service. The Eckstein group of mines have converted the steam winding engines on

their mines for electrical operation, wherever the plant was in good enough condition to warrant this.

A number of the winding engines are driven through gearing, whilst the others are driven by motors direct coupled to the drum shafts. The geared winding engines are driven by motors running at a speed of 360 revs. per min. The motor drives the drum shaft through single reduction gearing, of the straight tooth type in a few cases, but mostly of the double helical type with machine cut teeth. The slow-speed shafts are coupled to the drum shafts either by Oldham couplings or crank discs with drag links. In certain cases, where the speed of the drum shafts is suitable, the motors drive the drum shafts directly, the connection between the motor and drum shafts being made by means of couplings as mentioned above.

Several large existing steam-driven winding engines are also being converted for electrical operation by means of direct coupled motors. The peak loads on the motors of these engines vary widely, the smallest peak being about 400 H.P., and the largest peak output of the motors for winding engines for moderate loads and depths being about 2,000 H.P. The peak loads on the motors driving the converted winding engines used for heavy loads and depths of about 4,000 ft., are from 3,600 to 4,000 H.P.

In addition to these converted winding engines, a large number of new electric winding engines are being installed, having motors of varying maximum outputs from about 400 H.P. to nearly 6,000 H.P. The higher figure is the peak horse-power of the motors driving the two largest electric winding plants ever yet built, and which are capable of raising a net useful load of 8 short tons from a depth of 4,000 ft. and at a maximum speed of over 50 ft. per second. These winding engines are driven by two direct-current motors, controlled on the Ward-Leonard system, in conjunction with a motor-generator, without flywheel storage. The drums of these engines are cylindro-conical so as to reduce the peak loads to the minimum.

By far the greatest number of the winding engines on the Rand are equipped with three-phase motors with liquid rheostatic control. In special cases, where comparison between the three-phase system and the alternative system employing Ward-Leonard control and direct-current motors on the winding engine shows considerably in favour of the latter, the Ward-Leonard system of control has been adopted.

It is worthy of note that out of a total of over 100 electric winding plants, not a single Ilgner converter set is to be found, and the number of plants operated on the Ward-Leonard system is a small proportion of the total, although the two largest plants are equipped on this system. The Ilgner flywheel storage system has never been looked upon with favourable eyes by the engineers on the Rand, who, as practical men, recognise that simplicity and absence of complication in the winding plant are more valuable in the long run than a slightly lower running cost.

It might be anticipated that the power company would set limits upon the maximum momentary peaks for each consumer, so as to avoid the sudden throwing on of heavy peaks on to the station when a number of large winding engines are started together. No such limits are specified, however, as it is expected that the fluctuations in the total load on the power station will not be very considerable, owing to the large steady load due to the use of motors for other purposes on the mines, and also because the peaks from the various mines are not likely to coincide, but will cancel out to a great extent.

When all the electric winding plants now being installed are in full operation the total horse-power, and also the number of motors used for winding purposes, will be larger than can be seen within a similar restricted area anywhere else in the world. The winding problem has been boldly faced and treated with the practical common sense that is one of the characteristic qualities of the engineers on the Rand, and the systems used have been adopted, not at haphazard, nor by slavishly following European practice, but after careful study and selection of the systems best suited to the conditions of the country and its mining methods.

In closing these remarks it must not be forgotten that the conditions on the Rand are quite unlike anything met with in Europe, as many of the vertical shafts are 4,000 ft. deep, and the unbalanced loads on the engines due to the rope when hoisting from this depth are enormous. When men are being lowered down these shafts, therefore, three-phase motors have to run under counter current, and the problem of designing safe and satisfactory controlling gear for such conditions is not an easy one, owing to the large amount of energy which has to be dissipated in heat in the rheostats, at voltages considerably above the normal rotor voltage.

In the case of some of the larger winding engines on mines belonging to the Eckstein group, where these conditions are exceptionally severe, electromagnetic brakes are being provided on the motor or drum shafts, for use in case of failure of the supply, or in addition to the usual mechanical brakes. Engineers are divided in their opinions upon this feature, which is a new and untried one in winding plants, and it is still to be seen whether this brake will do what its proposers expect, or whether it would not have been safer and preferable to provide Ward-Leonard equipments for the winders in question, as recommended by the leading Continental firms, who have had a wider experience of three-phase winding plants than any of the British firms, and therefore better appreciate the peculiar difficulties to be overcome in these cases. This and many other points will be cleared up in the course of a few months, when the plants are put into operation.

Air Compressors.—Next to winding plants the largest motors are to be found in air compressor plants. As stated above, the largest air compressors are those installed in the Power Company's stations at Rosherville and at Robinson Central Deep. These compressors are of the rotary type, divided into two stages, and provided with water-jackets on the casings. The air is delivered at about 110 lb. per square inch. The characteristic curves of the rotary compressor for volume and pressure are very similar to those of the centrifugal pump, a drop in pressure resulting in the quantity of air supplied being increased, so that the load on the motor increases as in the centrifugal pump motor.

The motor-driven rotary compressors are supplied with synchronous motors of similar design to a turbo-generator, and of 4,000 to 5,000 H.P. output. The reciprocating compressors do not require anything approaching this power. The maximum is about 1,500 H.P. Motors of the synchronous type as well as the induction type are used, according to the conditions.

The object of using synchronous motors is to make these serve as power-factor improvers, by over-exciting the fields, so that the power-factor of the whole local distribution circuit is raised. Where a number of air compressors are installed in one station, both induction motors and synchronous motors are used, the latter on one or more sets only, so as to counteract the low power-factor of the compressor motors (slow-speed induction type), winding plant motors and other induction motors, at that particular sub-station. The synchronous sets are started up by special auxiliary induction motors coupled through gearing and clutches to the compressor shaft, compression being relieved whilst starting up.

Locomotives.—Until recently electric locomotives had not been much used, and the number now in use is not large. The largest and most interesting are a number of three-phase locomotives for use on the City Deep and Crown mines for pulling trucks on 3 ft. 6 in. standard gauge lines on these mines. The rating of these locomotives is about 300 H.P., which is developed by two three-phase motors each of 150 H.P. The motors are placed high on the frame of the locomotive, and drive a countershaft through spur gearing, this countershaft having crank discs at each end, which transmit the power to the driving wheels through vertical and horizontal coupling rods. Two overhead trolley wires are used, with the rails as third conductor of the system. The operating voltage on the trolley wires and motors is 2,000 volts. Each locomotive is provided with air compressor and vacuum pumps, electrically

driven. The locomotives are each composed of two half locomotives, which are normally close-coupled together and run as one unit. When necessary the two halves can be uncoupled and used separately, each dealing with half the load which the complete locomotive could handle.

Haulages and Conveyors.—The motors used for haulages vary from about 20 H.P. to about 75 H.P., and are usually of the slip-ring rotor type; whilst conveyors require motors of 7½ H.P. and upwards. There is nothing special in this application of electrical driving.

Stamp Mills.—These form one of the largest applications of electrical power on the mines, and also one of the most important. The mills are very seldom shut down, so that the motors employed must not be too heavily rated, and must be of robust construction.

The chief requirements for motors for this use are :—Robust construction. Ample bearing surfaces, with strong shafts and automatic lubrication. High starting torque. High efficiency and power-factor.

The first requirements ensure satisfactory running for long periods without attention. The last three requirements are also vital, as they affect the running costs of the mills.

The question of the different methods of driving stamp mills has been widely discussed, and there are still different opinions as to the best type of motor and best method of driving. In the case of the East Rand Proprietary mines, the stamp mills are connected in groups to separate line shafts which operate the stamps directly. The motors run at 104 revs. per min., and the rotors are connected direct to the line shafts. As the frequency is 25 cycles, the power factor and efficiency of the motors are good, and losses in ropes, belts, or gearing are avoided.

The motors are exposed to severe vibration from the stamp mills, and in case of any breakdown the time spent in repairs means stoppage of the stamp mill driven by the faulty motor, as there is no chance of using a spare motor. A number of the stamp mills on the Eckstein mines are also driven by similar slow-speed motors. running on a frequency of 50 cycles. The large new stamp mills of the Randfontein Estates, on the contrary, are driven by high-speed motors. This is the largest stamp battery in operation on the Rand and contains 600 stamps, each weighing 1,650 lb., arranged in units of 10 stamps. Two such units (totalling 20 stamps) are driven through countershafts by motors of 100 B.H.P. These motors are of the squirrel-cage type with compensator starters.

The new stamp mills of the Roodepoort United Main Reef G.M. Co. (General Mining & Finance Corpn.), containing 100 stamps, each of 1,901 lb. weight, are driven by 50 B.H.P. motors of the squirrel cage type with starting compensators, each motor driving by belt on to a countershaft, working 10 stamps. The preference shown for the squirrel-cage type of motor for this work, is due to the absence of slip-rings and sliding contacts in these motors. There is always a certain amount of vibration present, and this, combined with grit, sooner or later causes trouble with the slip-rings. The efficiency of the squirrel cage motors used is somewhat lower than that of the slip-ring type, owing to the necessity of designing the motors to give a high starting torque—the difference in efficiency is of the order of 1½ to 2 per cent. in favour of the slip-ring motor. This is considered as compensated for, however, by the reduced risk of stoppages obtained by using the squirrel-cage type of motor.

Tube Mills.—Tube mill motors are required to fulfil practically the same conditions as for stamp mills. The starting torque requirements are, however, even more severe than for the latter, 200 to 250 per cent. of normal full-load running torque being often necessary to start the tube mills. Slip-ring motors are perferable for this duty, and have given entire satisfaction. The motors are usually of 60 to 100 B.H.P. and run at 600 revs. per min.

Pumps.—The number of pumps employed in the surface plant of a gold mine is considerable, and this forms quite a good motor load in itself. For a surface plant comprising 100 stamps, the total horse-power of the motors installed for pumps may reach 600 B.H.P. The pumps are mostly centrifugal pumps of the "Morris" type, driven by direct-coupled motors. A pump is usually installed as a spare for the tailings wheel, so that the latter can be cleaned or repaired without stopping the mill.

Tailings Wheels.—The motors used for driving the tailings wheels are of 35 to 50 H.P., usually driving by belt on to reduction gear, as the speed of the wheels is very low. Owing to the large amount of inertia to be overcome when starting the tailings wheel, high starting torque is required, making the slip-ring motor most suitable for this work.

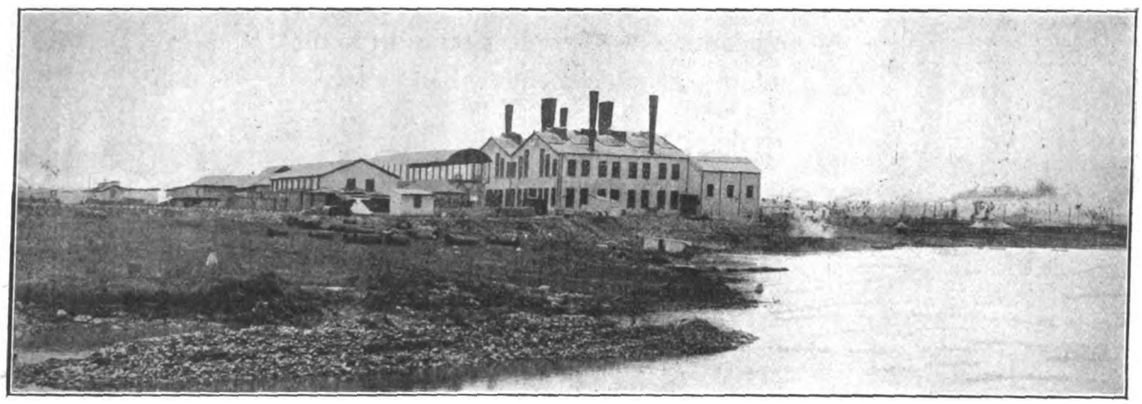

FIG. 5.—GENERAL VIEW OF SIMMERPAN POWER STATION.

Other Uses.—In addition to the applications mentioned, motors are used for many other purposes, such as driving crushers, sorting belts, shaking tables, rock hoists, elevators, extractor house plant, &c., but there is nothing of particular interest in these uses.

Underground Uses.—Owing to the great depth to which the Rand mines are now being worked, it is necessary to do the hauling of the ore in two stages in some of the deeper mines. The deepest vertical shafts are just over 4,000 ft. in depth, and it is intended to work down the slope of the reef to an ultimate depth of about 10,000 ft. Winding engines are therefore being installed underground at the bottom of the main shafts, to haul the ore up the incline and deliver it to the main winding engines which haul the ore to the surface.

These underground winding engines are also being electrically driven. Owing to the comparatively small depths from which they are at present hauling, the motors required are not of the same large sizes required for the surface winding engines, but in the near future the power requirements for underground haulage will increase very considerably. The only special point of interest in these winding engines arises from the fact that the whole machine must usually be sectionalised, to enable the parts to pass down shafts of limited dimensions. This affects the whole design of the plant, in limiting the sizes of the drums, and, therefore, indirectly settling the speed and type

of motors, and often making the use of gearing compulsory. It is probable that most of the underground winding engines installed will be driven by three-phase motors. There are a number already in operation and more in course of erection.

Pumping Plant.—Up to the present time the centrifugal pump does not appear to have met with much favour on the Rand for underground pumping. The plunger pump is widely used, and appears to have given every satisfaction.

There are signs of a more extended use being made of the centrifugal pump, and should the results prove as satisfactory as they have elsewhere, this type of pump will probably be much more widely used.

Locomotives Underground.—Electric locomotives are not used anywhere underground on the Rand (so far as the author knows), and although trials have been made with petrol locomotives, no information is yet available regarding the results. There appears to be a number of cases where electric locomotives could be employed underground with advantage, but labour appears to be so cheap that engineers are doubtful whether electrical haulage could be substituted with economy.

This question appears to be receiving consideration by the engineers, however, and probably it will not be long before a trial installation will be put down somewhere, where the conditions appear to be favourable. In view of the large number of successful installations of underground locomotives on the Continent, there is certainly good reason to anticipate that the introduction of electric haulage underground would be economical on the Rand in mines where favourable conditions exist. Apart from the above purposes, electricity is only used underground for lighting.

The foregoing gives an idea of the great developments that have taken place on the Rand in the extensions of the use of electricity. There is no gainsaying the fact that the formation of the power supply company has to a great extent accelerated these developments, and in the absence of a cheap supply of electrical energy in bulk, the Rand would not occupy the position which it very soon will, as the best equipped goldfield in the world, containing more new applications of electricity, and these on a larger scale, than any other mining centre can boast of.

Diamond Mines.—The conditions existing in diamond mines, and the plant required, are essentially different from those met with in gold mines, and there is not so large a field for the application of electric driving. The De Beers Company have a large power station equipped with turbo-generators for supplying energy to the mines, and also for lighting the town of Kimberley. Electric winding is not used either on these mines or on the Premier Diamond Mine. Motors are used for driving haulages, conveyors, crushers, washing plant and for pumping and lighting.

The conditions of hoisting are not so favourable to the use of electric winding plants under present conditions as those existing in gold mines. In the Premier Diamond Mine the ground is hauled from the mine, which has open (quarry) workings, by an endless wire rope haulage, which is driven by an economical type of steam engine, running on a practically constant load; this engine is installed in the power station. Under these conditions it is not easy to make out a good case for electric winding. As the mine increases in depth, however, the conditions will be unfavourable for any extension of this system, and more favourable for the use of electrically-driven winding plant.

The quantity of blue ground hoisted per day is about 50,000 short tons, and from this the magnitude of the plant required can be gauged. Electrically-driven haulages are used in the workings as feeders for the main haulage, and a number of motor-driven centrifugal pumps are in use. The workings are lighted by arc and incandescent lamps. The power house has been in operation for some years, and is not, therefore, worth special mention.

Rhodesian Gold Mines.—Such far-reaching developments as have taken place on the Rand goldfields cannot be anticipated in a country like Rhodesia where the gold mining industry is now only in its early youth, as compared with that of the Rand. In fact, there are underlying differences between the mining conditions in the two fields. The Rand gold bearing reef has been closely delimited, so that its contour, extent, and slope are fairly accurately known, as is also the grade of the ore. Under these circumstances, mining becomes practically a purely commercial proposition, working expenses on the one side, and value of the gold recoverable per ton of ore being known, whilst the grade of the ore is known to be practically uniform within narrow limits.

In Rhodesia no reef at all resembling the Rand Reef has been located, the majority of the reefs at present worked being much richer than the Rand reefs, but patchy and variable in depth. Moreover, water is mostly scarce in Rhodesia, and coal is very dear. In consequence of these conditions, a mine with a 40-stamp battery is a large mine in Rhodesia, where the majority of the mines have five, 10, and in a few cases 20 stamp plants. For such small plants there is, of course, practically no scope for the use of electricity.

The bigger mines, however, have put in electrical power plants, where the conditions are suitable. The mining centres are widely scattered, and this condition is not favourable to the installation of central power stations for giving a bulk supply of power to the different mining centres.

Owing to the scarcity of water and cost of coal a number of the mines have installed suction gas engine plants for driving their machinery. The fuel used is wood charcoal, but many of the mines are already finding difficulty in obtaining sufficient fuel, having denuded the country of timber round the mines, and thus having ever-increasing fuel transport charges to face.

The Bushtick Mine has a large suction gas engine plant, comprising two 230 B.H.P. gas engines with producers, belt driven, 60 cycle, alternators, and a number of motors. The generator units are run on separate circuits and cannot be operated in parallel, which must detract from the flexibility and economy of the plant. The working costs are low, and the attendance required by the plant is confined to the periodical stoking of the producers by native labour. Difficulties have been experienced in a number of these plants owing apparently to the effect of the altitude upon the engines not having been sufficiently appreciated by designers, but, on the whole, such installations appear to operate satisfactorily.

Electrical driving is also extensively used on the Globe and Phœnix Mine, Giant Mines and Jumbo Mines, which have steam-driven generating plants, and motors for driving most of the surface plant except the winding engines, which are steam driven.

Sufficient has been said to show the present position of the Rhodesian mines as a field for the operations of the electrical engineer, and whilst large developments are not to be expected for the present, yet the mining resources of the country are comparatively speaking so unexplored that no one can safely foretell to what extent electricity may be applied in the mines of Rhodesia in the future when this country has been really prospected and its mineral resources opened up.

In closing this necessarily brief account of some of the work that has been carried out by our brother engineers in South Africa during the last two or three years, the writer tenders his thanks to the mechanical and electrical engineers responsible for the installations referred to for their courtesy in furnishing information concerning their installations.

If the relations between engineers in this country were as free and easy and untouched by professional jealousy as is the case in South African engineering circles, it is probable that both the engineering industry and those connected with its well-being would be the gainers, and that progress would be accelerated. Mutual exchange of ideas, friendly criticism, and discussion between the engineers engaged in tackling the various comprehensive schemes of electrification on the Rand, have certainly helped forward the progress of electrification.

The results of the working of the several large electrification schemes now nearing completion will, no doubt, be watched with great interest in this country, as well as in South Africa, and it is to be hoped that the enterprise and boldness displayed by all those concerned in the initiation and carrying out of the work will be crowned with well-merited success.

The Elimination of Risk in the Use of Electricity in Mines.

BY PROF. W. M. THORNTON, D.SC., D.ENG., M.I.E.E.

Summary.—The risks that are here particularly considered are those from explosion and from shock. Risk of explosion from switch boxes and fuse boxes can be eliminated by adopting a simple flame-proof method of construction. Danger would be eliminated if the supply of electrical energy were cut off whenever gas is present, and automatic apparatus for this purpose has been devised; but this has to stand the test of practical working before it is generally adopted. There does not seem to be much risk from electric oscillations giving rise to sparks (from armoured cables) of sufficient energy to cause ignition. Danger arises from coal dust as much as from gas, but risk from the former may be eliminated by certain precautions. Risk of shock can be overcome by effective earthing. It is suggested that a certain number of mining electrical engineers should be appointed amongst the new sub-inspectors.

The Report of the Departmental Committee recently issued marks the end of the second stage in the use of electricity in mines. The first was that of direct current on a small scale for pumping and haulage, with some lighting, ending with the Report of the Committee appointed in 1902. The last seven years have been remarkable in the history of coal mining in this country and abroad, for the introduction of electrical power on a scale unthought of 10 years ago. The special features of this increase have been the emergence of the three-phase system, and a very necessary improvement in the mechanical construction and enclosure of machines and distributing gear.

It was inevitable with so flexible and powerful an agent placed in the hands of men who, as attendants, could not be, by the nature of the case, highly skilled in the working of electric plant, that risks should be taken which, it is not too much to say, would not have been taken in well-equipped workshops above ground. The old-fashioned switchboard, for instance, consisting of a wooden panel with a few open-type switches and fuses, placed across a corner to give access behind, and guarded or not in front by a hand rail, which was and is still to be seen in medium pressure colliery installations, was only safe because of the small power handled, its limited range of application and the few men required. To have extended such a system a hundred-fold would have been to court disaster, and it speaks well for the quick response of the electrical industry that, when large powers and higher voltages came into use, the generating and distributing systems rapidly improved. But even in the few years that electricity has been used in mining, habits have had time to be established. In the old days, before electricity, it was the chief duty of the colliery engineer to design apparatus to be made at the colliery. This habit, good in many ways in mechanical engineering, has been extended in the present day to electrical gear, with results which are not so good. In fact, it may be said that at the present time the greatest risk in the use of electricity in mines lies in the number of home-made or designed use, switch or distribution boxes and similar devices to be found in almost every installation. The design of these is sometimes excellent, but more often primitive, and so long as this class of apparatus remains in use there is risk from it. If there is one part of mining plant of which the quality fluctuates more with price than another it is the electrical. The difference between "that will do" and "that's a good thing" does not, as a rule, mean 25 per cent. on the total capital cost of auxiliaries as distinct from the main machines, and it is generally worth it in the underground equipment.

The first thing, then, to do in the third stage of electrical development now beginning is to eliminate risks due to imperfect gear accumulated in the past, whether in ignorance of possible danger or from false economy. This is emphasised by the new Report under the head of "Proper Construction and Good Maintenance necessary for Underground Work." The present would be a suitable time for a manager having doubts about any part of his equipment to revise it in the light of the Report.

The specific dangers which may arise in the use of electricity below ground are (1) ignition, (2) shock. The gas (methane) given off by coal seams is readily ignited. Like all inflammable gases, its behaviour when ignited may be regarded in two ways. In the first place, if an enclosure is quite full of a mixture of air and gas, in which the proportion is about 20 per cent. or more of gas, a flash or flame will not ignite it provided the flash takes place within the gas. The mixture has not enough oxygen to support combustion. If, again, a flash takes place at the lower surface of a body of gas which has accumulated slowly, there is not a violent explosion; the flame travels along the gas layer, picking up its oxygen as it goes, often returning and even passing to and fro several times, disturbing the gas by its heat and movement, until, if there is a sufficient quantity of the latter left, an explosive mixture is formed and there is a detonation. Since these slow accumulations are invariably near the roof—methane being much lighter than air—it follows that where there is even the remote possibility of the presence of gas, fuse boxes, switch boxes, even distribution boxes without fuses, should be kept *as low as possible* and never placed high against the roof.

Wherever it is absolutely necessary to use such boxes in places where gas may enter it is, however, possible to prevent danger entirely from anything of the nature of a flash or miniature explosion which may take place within the box. The improved boxes are known as flame or explosion proof, and are based on the simple device of providing the cast-iron containing box and lid with a planed flange about 1¾ in. wide, so arranged with bolts not more than 5 in. apart that the lid flange beds uniformly all over its surface, metal to metal. No rubber joint is necessary, or indeed advisable, the essential principle upon which the construction is based being the cooling of the flame and hot gases of the internal explosion to such a degree that when they blow out through the exceedingly narrow space between the lid and box they cannot be seen, nor can they ignite gas outside the box. Like other good things, these boxes are not, however, quite fool proof. They depend upon having flanges clean when bolting up, upon having the bolts well and truly secured, and upon the efficiency of the leading-in stuffing boxes; but they are an enormous advance on much that is in present use.

The simplest way of eliminating danger from gas is to cut off the electrical supply the moment gas is observed near the electrical gear, and to do so at some remote point—not at the gear in question unless fully enclosed. This rule (15) if rigorously obeyed would go far to remove the objection which is sometimes expressed to the use of electricity anywhere in coal mines. If the gas is in small quantities it can generally be removed quickly. Needless to say, large quantities should not be present, unless they occur accidentally by reason of a fall or sudden break of roof. Except under conditions of urgency, such as might occur in dealing with a rush of water, it is difficult to justify in general the risks taken in the use of electricity in places where gas may be present in an explosive mixture. It cannot, however, be too widely known amongst mining men that electrical apparatus can be made, and is made, to work under any conceivable conditions with perfect safety; but until such apparatus is universally used, and is fool proof, greater safety lies in keeping electricity at a distance from gas, as the rules direct.

SPECIALISTS IN INSULATING PROTECTION FOR ELECTRICAL WORKERS

Gloves & Gauntlets.

Our New Type of insulating Glove is protected on the palm by a special form of **FLEXIBLE LEATHER FACING**, which—

(1) **Increases the safety.**
(2) **Protects the rubber rom wearing.**
(3) **Protects the rubber from oxidization.**
(4) **Hardly decreases the flexibility.**
(5) **Is practically unaffected by wet.**
(6) **The gloves are easily put on and taken off.**

Special attention is directed to the fact that EACH Glove is tested, and not one out of batches.

Each Glove bears a Certificate similar to notice below, but varying as to voltage.

This Glove
has been tested in water to
10,000 VOLTS A.C.
FOR 5 MINUTES.

Each Glove also bears our name and address, to ensure repeat orders.

Digitized by Google

A device has been recently introduced for the purpose of automatically cutting off electrical pressure by the heating of a platinum wire operating a switch relay when gas accumulates in dangerous quantities. If this can be made to work under all conditions of hard usage, with pilot cables thoroughly safe and the gear operated by current at low pressures, it will be most useful. Before, however, it can hope to be generally adopted it must be demonstrated that there is absolutely no risk in its use or under any condition of working.

A suggestion has been recently made that there might be sparks from electrical oscillations induced on the sheath of a lead-covered or armoured cable by the high-frequency oscillations of current which occur at the moment of interrupting a circuit by a switch. The suggestion is one which must be considered, for to prevent such oscillations the earthing of a sheath has to be continuous—that is, every few yards should be earthed! The only question is whether the energy of a spark formed in this way could be sufficient to fire gas. From experiments by the writer it appears that short, thin, high-tension sparks between copper wires in an explosive mixture do not ignite gas provided that the wires are nearly touching. There seems to be, as it were, a certain volume of spark necessary to ignite gas, in the same way that there is a minimum flash for the ignition of coal dust. On the other hand the sparks obtained from conductors upon which electric waves from a wireless transmitter impinge, can readily ignite gas. A risk of this kind may be classed as remote in practice, but until definite experimental tests have been made on a large scale it cannot be dismissed. Should the induced sparks be found in any case strong enough to ignite gas there is no remedy but to remove the plant. In the opinion of the writer there is not, from the preliminary trial, much likelihood of this being necessary, especially with three-phase systems.

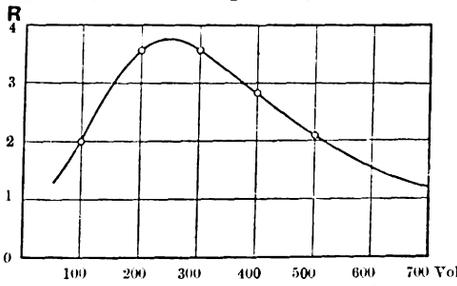

FIG. 1.—COMPARISON OF SAFETY OF ALTERNATING AND DIRECT CURRENTS.
R=Ratio of least Alternating to least Direct Current to produce ignition of Coal Dust.

Although it has been known for over 30 years that coal dust is an active agent in transmitting mine explosions, it is only within the last year that it has been shown to what degree it may be ignited directly by electric flashes. Any powder containing volatile matter, provided that it is finely divided and freely supplied with oxygen, can, under suitable conditions, burn so rapidly as to give a detonation. To cause this to take place a certain size of flash or flame is necessary. In general it may be said to be about the size of a safety lamp flame, though there are no records of dust being ignited by a sound safety lamp in the absence of gas. The dust which can be shown to be most sensitive to ignition is the very fine powder found on the roof and timbers. If by an accident such as a fall of roof there is enough vibration, either of the ground or air, to shake some dust down into suspension, the conditions are right for the transmission of a flash occurring at a broken cable, or a fuse blowing in consequence of damage done by the fall. Two steps, however, are usually necessary—the disturbance of the dust and the flash following. Under certain conditions these may be merged into one. There may be fixed, close to the roof, a fuse box which is not flame proof, or one in which there may be a short-circuit between the line terminals or to the frame, set up by the blowing of the fuse. Such a violent arc is of the nature of a miniature explosion, and can be shown to disturb dust in its immediate neighbourhood. If this is of a highly combustible nature—and most of the great dust-transmitted explosions of late years have been in seams giving readily ignited dust—the flame is continued by a small external ignition, not a detonation. This disturbs more dust, and the process continues, with the flame travelling and the pressure rising, until the ignition becomes a detonation and the great damage begins.

The first point in the elimination of risk by direct ignition of coal dust by an electric flash is the provision of cables, fuse and switch boxes of such a design that no flame can emerge though there may be flashes within. In addition to this there should be no possibility by the omission of insulating fins or by imperfect design, of so violent a short-circuit developing that the box is broken. Such things are not unknown.

Where unarmoured cables are secured to the roof timbers they should be far enough apart to render remote the possibility of their ends coming into contact in the case of a fall breaking the cables. In addition to this, they may be at the time carrying current. In the case of medium pressure direct current the flare may be considerable, especially if the break draws out slowly. There is no remedy for this. Unarmoured cables are out of place in a mine, unless they can be fixed in such a position that there is no danger of their being broken, or that there is no coal dust or gas in their neighbourhood.

The risk of ignition depends very greatly on the electrical pressure used. Figs. 1 and 2 (which are reproduced by permission from the "Transactions" of the Institute of Mining

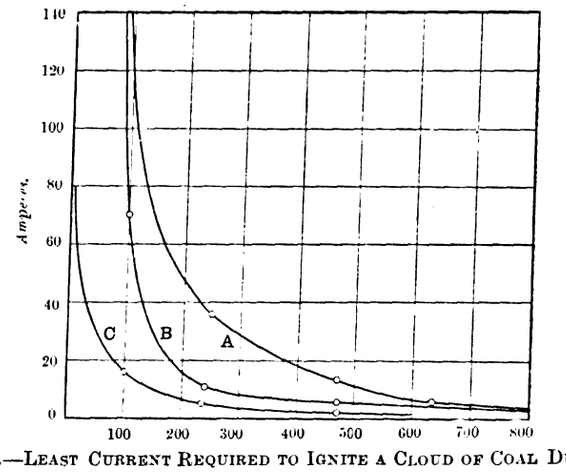

FIG. 2.—LEAST CURRENT REQUIRED TO IGNITE A CLOUD OF COAL DUST WHEN THE CURRENT IS INTERRUPTED BY A QUICK BREAK SWITCH.
A, Alternating Current Power Factor, 0·8; B, Direct Current, Non-Inductive; C, Direct Current with some Inductance.

Engineers) show very clearly the advantage of the use of low pressures, especially with alternating currents. They also illustrate the very great gain by the use of alternating currents, so far at least as the risk of igniting coal dust by their interruption is a determining factor.

The amount of coal dust necessary to transmit a dust explosion is about one gramme per cubic metre of air. Such a quantity is frequently found, especially where high-speed haulage is used. The most direct way of obtaining safety from it is by preventing its formation. This can be done at the start by the use, for example, of hydraulic power to bring down the coal wet, and by enclosing tubs as thoroughly as possible. It can be removed to some extent by brushing, or, much better, by a fan collector. It can be kept down by sprinkling with water, or, a more recent suggestion, by the use of a binder, such as soap or caustic soda with water glass in the water. In a mine with the coal dust either removed or fixed, the danger of a local ignition of gas spreading through the workings would be entirely removed. This would not, of course, lower the standard of electrical plant, for all the conditions which apply to safety against ignition extend to prevention of shock.

It is probable that many explosions are initially propagated, though not started, by a weak mixture of gas and dust. This is more dangerous than either alone, for while it requires about 6 per cent. of gas to be dangerous, or a dense local cloud of dust, from 1 to 2 per cent. of gas is sufficient, when mixed with dust, to continue an ignition with violence. These points do

not seem to be quite fully appreciated either by mining men or electrical engineers. Danger from safety lamps may be said to begin when kept alight in 6 per cent. of gas ; but a much weaker mixture in a dusty place would be ignited with ease by a flash, whether electrical or otherwise, of the size of a match flame. This should be demonstrated in every colliery centre.

With regard to risks from shock, Appendix B to the Committee's Report shows the proportion of deaths from shock to those from electrical ignition to be seven to one. It should be known that the intensity of a shock is not in the first instance proportional to pressure. In other words, it is current that kills, so that a low pressure operating on a person whose resistance has been lowered by working in a moist atmosphere or by freely perspiring, may be fatal. From 80 to 100 volts is the lowest which, under the most unfavourable circumstance, may be regarded as dangerous. A severe shock can be had from 50 volts with hands moistened with slightly acid water ; and with a weak heart there might even then be danger.

If every part which could be touched by the hands were efficiently earthed under all conditions of normal working danger from shock would be eliminated. An analysis of the cases of shock in the above appendix shows that out of 53 cases in which there was no doubt of the cause 27 were from abrasion of cables, 19 from apparatus, switches, controllers, &c., and seven from machines, chiefly coal cutters. In view of the increasing number of deaths from shock the merit of the new rule as to armouring cannot be questioned, though it will no doubt be felt by some to be stringent. One of the first duties of the new sub-inspectors, so far as the use of electricity is concerned, will be to learn the details of efficient earthing.

In reference to this it may be opportune to point out that rarely in the progress of any industry has there been such an opportunity for ensuring that new rules should be efficiently carried out. An important part of the inspectors' work will be the review of the electrical plant ; but unless each one has special electrical knowledge this is likely to miss fire. Would it not be possible to appoint amongst them six men not primarily miners, but mining electrical engineers, one for each of the great divisions (Scotland, the North of England, Yorkshire, the Midlands, Lancashire and South Wales), whose first duty should be to go round with and instruct the others in electrical matters ? A year or two of instruction of this kind would do more to raise the level of general knowledge of electrical work amongst mines inspectors than much indirect experience, and would no doubt benefit manufacturers by improving the demand for higher class apparatus. Since the Committee have decided not to approve officially certain types or designs of apparatus, it is all the more necessary that some uniformity of standard should be more or less agreed upon by those whose work it will be, amongst other things, to inspect plant. The confusion at present is infinite ; every variety of electrical apparatus, from the best to the worst, is found in coal mines, and although it is perhaps impossible to expect the same standard of outlay in a small struggling colliery as in great combines, there is no reason why the worst should be anywhere permitted.

The six general heads under which the Committee summarise their work show that they consider the time has come for a general "tuning up" of the use of electricity in mines. It has of necessity to be withdrawn where there is risk of ignition ; mechanical construction shall not favour an ignition in a motor room spreading ; shock is to be avoided by complete earthing ; switchgear is to be efficient and under a responsible person ; both switchgear and cables are to be made mechanically stronger ; the manager must formally appoint an "electrician," who will systematically report to him. These are so great an advance from the point of view of safety and reliability that it is not too much to say that they mark a new era in the use of electricity in mines in this country. It only remains for workmen, managers, manufacturers and inspectors to co-operate in making them effective.

Special Risks in the Application of Electricity to Mining Work under S. African Conditions.

BY H. J. S. HEATHER, M.I.E.E.

Summary.—Attention is drawn to the special conditions prevailing in South African mines, and the subject is discussed from the points of view of (1) safety as regards life, (2) safety as regards plant, and (3) safety as regards continuity of service. These points of view are each liable to be given extreme importance, depending upon the position of the individual. In South Africa, ignorance, curiosity and wilful tampering are important factors. A table is given showing the conditions under which shocks may be received, and the question of protection by earthing is considered, the conclusion being reached that the neutral of a three-phase system should not be earthed.

In its capability of being safely operated by unskilled attendants, when once it has been properly installed by skilled engineers, electric plant exhibits one of its greatest virtues. But the skilled engineer must remember to guard against the defects which this quality involves ; the ignorance of the unskilled attendant in mining work can, and does, attain proportions that at first sight would seem quite impossible. The writer's experience may, perhaps, in this direction be wider than that which most people have had the opportunity of collecting. He has had to deal not only at home with the English miner, but in the Transvaal with Boers, Kaffirs and Chinese, and he has found that the degrees in which astuteness and simplicity are combined in these different classes of labourers present an extraordinary amount of variation. He has had cases where it has been found necessary to keep bare copper overhead wires alive in order to prevent them being cut up to make bangles, and where leather belts have been kept running 24 hours a day so that they might not become boot soles. An ignorant white colonial attendant has suggested to a mine manager, to whom energy was being sold by meter, that putting a solution of sal-ammoniac into the meter would cause it to read slow, to the great advantage of the consumer.

The failure to realise the danger that may lie in touching electrical wires and apparatus is, of course, not to be wondered at. The dread of great heat is perhaps by now instinctive in the human race ; but in all probability, if this is so, we have only got at present far enough to dread heat when it is accompanied by light. One still has to learn that in a tropical climate one cannot pick up pieces of iron that have been lying in the sun, just as the newcomer on a mine has to learn that drills in the sharpening shop may be unsafe to handle. For very many years to come, therefore, we cannot expect that the ordinary person will look upon the wire or terminal as an object of suspicion because it may be electrically charged.

The question of safety in using electricity for mining operations can properly be divided into three headings :—

1. Safety as regards life.
2. Safety as regards plant.
3. Safety as regards continuity of service.

Digitized by Google

According to the point of view from which one looks at these three requirements, one or other of them is liable to assume undue prominence. The Government Inspector, for instance, sees the first very much in his foreground, and the second and third nowhere. To the consulting engineer the second assumes exaggerated proportions, and the mine manager is often liable to pay too little attention to the first and second, and to regard the third as the only justification for the existence of the electrical plant. Now, although one fears that one may be accused of callousness if one questions the correctness of the Government Inspector's view, the real fact is that the whole question is one of probabilities, and a balanced idea of the relative importances of the various objects can only be obtained by a man who has had a long and intimate experience of the risks involved.

This, of course, does not apply only to mining. No one, for instance, would question the advisability of periodically painting steel bridges, which means choosing to take the small chance of losing a man employed to do the dangerous work, in preference to the practical certainty of having to pay for expensive deterioration. In all businesses chances must be taken; but as, according to the insurance companies, mining is one of the employments most dangerous to life, and, according to Stock Exchange quotations, it is also one of the most risky investments for capital, it is clear that the risks that have ordinarily to be taken in electrical mining work, both as regards fatalities and plant breakdowns, are likely to be greater than those that have to be met in the application of electricity to most other work. The art has to suffer from the circumstances of its environment, and it is likely that this state of affairs will be, to a great extent, permanent, for although some of the extra risks are avoidable, others must be regarded as more or less inherent.

Amongst the latter are to be included those due to the fact that in a mine cables have very generally to be put in such positions that throughout their length they are within reach of the passer-by. The dampness of the normal atmosphere underground, the acidity of the mine water, in some places dust, the presence of non-conducting as well as conducting strata, falls of roof and sides of shafts, blasting in metalliferous mines and darkness, all contribute to the unavoidable risks.

Amongst the risks that we may hope we shall some day prove to be avoidable may be put those arising from bad work, temporary work (which very often is bad work), rough handling, ignorance and carelessness.

These avoidable risks have to be dealt with in various ways. There is no reason whatever why bad work should continue to be put in. It can at once be eliminated by employing none but skilled and conscientious workmen, and keeping them up to the mark.

The temporary work question is a little, but only a little, more difficult to deal with. Pressure is constantly being brought to bear upon the electrical staff on a mine, with the object of getting work done quickly without due regard being paid to the point as to whether it is done satisfactorily. To withstand this pressure successfully strength of character is required; it must be kept in mind that work that is originally intended to be purely temporary very often comes to be regarded as permanent, or at least semi-permanent. It is usually very difficult to persuade the non-technical mining man that there can be any necessity for stopping plant that is, to outward seeming working satisfactorily in order to effect what is to him a highly problematical improvement. His habit of thought, as a mining man, forces him to the opinion that accidents must occur, and that, particularly in connection with electrical work, the proper way to look at them is to a large extent as "acts of God." His inclination, therefore, is always to "let well alone." The easiest way to deal with this frame of mind is for the electrical engineer never to need to make improvements on running plant. He should set himself one standard as regards safety—namely, the best he knows of—and he should maintain this standard whether he thinks the work he is doing is permanent or temporary.

Other risks, those, for instance, due to ignorance and carelessness, will take far longer to eliminate. Education and experience can only extend by slow degrees, and they are needed to prevent the rough handling that is another source of danger to underground electrical plant. To the miner, the hammer takes the place of the spanner, and dynamite that of the screw jack; so if electrical plant is to be left in his hands at all it should be so designed as to be able to stand up against this sort of idea.

Amongst non-European workers curiosity may be a danger to be seriously taken into consideration. In this respect the writer has found in his experience on South African mines that the native Kaffir gives little trouble. His mental level is so low that practically all the white man's machinery produces in him an intellectual stupefaction. Everything alike is simply "tagati," witchcraft, and the things that appear to him the most wonderful are those that he can most nearly understand: that is to say, the very things that appear to us the least surprising. The consequence of this is that curiosity is almost atrophied in him. He has no desire to look inside anything because he has no reason to suppose that an investigation will leave him any wiser than he was before. The case was quite different with the Chinese during the time they were allowed to be imported into the country to make up the deficiency of native labour. Their inquisitiveness knew no bounds, and, as may easily be imagined, it formed a constant source of trouble on electrical plant. It may be regarded as a fortunate thing for many of them that they concentrated their attempts at research work largely upon the mine bell-signalling systems. Of course, with increased experience of the danger of meddling with electrical plant, there is no doubt that this curiosity would be held in check by a wholesome dread of possible results.

It would appear, therefore, that, so far as the uncivilised races of the world are concerned, it is quite possible that at a certain stage, an increase in intelligence among workmen may for a time increase instead of decrease the difficulties of running electrical machinery. If this stage exists it will not be of long duration, but apparently it will have to be passed through; there is no way of avoiding it.

In addition to this curiosity and ignorance, wilful tampering with electrical apparatus has to be guarded against. In the Transvaal the use by unauthorised persons of the shaft signalling bells has caused so many accidents that lock-up systems are being generally adopted, the keys being held only by those men who may properly convey instructions to the winding engine drivers. It is also not uncommonly found that switches of the air-break type, with covers that are easily removable, are put to illegitimate uses. In wet places underground they are found to form handy receptacles for anything that the miner wishes to keep dry. In metalliferous mines, candles, dynamite, matches and so on are often tucked away in them; in collieries most types of air-break switches are generally inadmissible, because of the possibility of gas or coal dust getting into them. To prevent the improper use of such switches as boxes, anything in the nature of a lead seal is quite useless. A fragile seal is only of value amongst persons in whom the respect for rules and regulations is strongly developed, and this cannot be said to be the case with the miner, whether white, black or yellow. The only way to make use of such switches is to make it really difficult to open them, by avoiding such things as wing nuts, making special box spanners necessary, and so on; but as in the writer's opinion most of these switches are radically objectionable underground, for reasons which will be mentioned later, he thinks that for power work in mines the extra cost of oil-break switches is always justified.

In the Transvaal the use of three-phase systems underground is so universal that up to the present the question of continuous-current switches in such situations has hardly had to be considered.

Practical joking is another direction in which ignorance finds a congenial outlet. It is often thought highly comic to give the unsophisticated Kaffir a shock. The direct danger to life in this sort of amusement is quite considerable, owing to

very different degrees in which different persons are susceptible; but, besides this, there is the indirect danger to be kept in mind. It is very likely that the Kaffir or Chinese will give a private repetition of the performance the white man has taught him, and it is unlikely that he will discriminate, even roughly, between a dangerous and a harmless voltage (if any voltage at all can really be considered harmless). Besides this, again, the sudden movement caused by an electric shock, which is in itself not dangerous, can often be quite unsafe in a mine working.

Proceeding now to consider the unavoidable risks, there is not much to dwell on in regard to darkness. The want of light makes it sometimes difficult to detect when things are not as they should be, and also makes it more likely that a man may inadvertently touch parts of machines, wires, &c., with which he had no intention of coming into contact. Exposed terminals should, therefore, be avoided as far as possible, and where they cannot be dispensed with they should be placed quite out of reach or in cages. It is quite wrong to imagine that safety to life can be secured by the use of any of the low voltages that are suitable for power work. Numerous cases of fatal accidents with voltages of 200, and even 100, will have come before anyone with much experience. In many cases it is practicable and advisable to put in better lighting, and with this, the protection of terminals and the use of increased care, the question of bad light is disposed of as far as it is possible to do so.

Falls of rock and blasting seldom do damage except to cables. Heavy armouring is a considerable protection. Whenever blasting is going on current should be cut off from any cable that is within the danger zone, not so much because of the fear of a short-circuit, as the circuit-breakers ought to take care of this, but from the danger of an exposed live core falling into water lying on insulating rock.

This brings up the combination that to the writer's mind constitutes the most serious of all the risks to life in underground work, that is the combination of an exposed live wire or terminal, water or conducting ground, and non-conducting rock. In all probability high resistance strata are more commonly met with in metalliferous than in coal mines, so that the risk now referred to applies with greater force to the former class of work. The climate of Africa, too, with its dry season of six months and an evaporation that is very high all the year round, tends to produce similarly dangerous conditions on the surface of the ground. A great many instances of the results of the rapid fall of potential over a short space might be given. In one case that occurred on a 10,000-volt plant in the writer's charge a native was killed by attempting to step over a live wire that had fallen from an overhead line and was lying for at least 70 yds. on the surface of the ground. In another instance a dog approaching a similarly fallen wire found when he got within a few yards of it that there was sufficient difference of potential between his front and hind feet to warn him that there was something wrong, and he fled, howling. On other mines where there has been no pressure in use above 500 volts it has been found impossible to step off the rock forming the floor of a drive on to a flat sheet lying on that floor without getting a shock, and one man was actually killed, apparently through touching the roof or side of a drive with his hand whilst standing on a heap of drills. Both he and all the drills were several yards distant from any electric cable, and there also the pressure in use was only 500 volts alternating.

There is, however, no need to multiply examples of the danger that may attend a leak that is not a leak to earth; that is quite common knowledge. What does, however, need emphasising is that this danger is particularly pronounced in mining work.

The principal reasons for this will also bear insisting upon. They are: The necessity of having long lengths of cable in easily accessible positions, the likelihood that the continuity of the armouring of the cables may be broken by the action of the acid mine water, and the fact that the hangers supporting the cables often have to be fixed in highly insulating rock.

The objectionable action of the mine water is, of course, not confined to the armouring of cables. Earth wires from the frames of machines are often eaten through, and leaks are established from any terminals to which a film of water can gain access. For this reason all such terminals should be supported on porcelain, and it should be kept in mind that even the water that condenses from the air is likely to be acid, as it will contain nitrous fumes from the dynamite used. It is this also that causes the writer's objection to air-break switches, with their accessible terminals.

But although the effects of mine water are deleterious not only to cable armouring, it is in this connection that they are the most likely to be serious, for the considerations given above show that when there is a leak to the armouring of a cable it is quite likely that a long length of the external surface may be raised to line potential and constitute a wide-spread danger. To avoid this some engineers decline to use armoured cables altogether, but this does not get over the difficulty, for the acid water running down a cable is often, in the event of a leak, just as dangerous as an armoured covering, and has, in the writer's experience, caused several fatalities even with the low pressures used for incandescent lighting.

It is this ever-present possibility of a wide-spread distribution of the line potential that makes the writer hold the opinion that for underground power work the neutral of three-phase systems should not be earthed, though he is aware that he is here treading on controversial ground. The argument that it is better to take a large risk of getting a shock at a certain voltage rather than a small one of receiving 1·7 times that voltage is not one that can have any practical application except over a very limited range of pressures; and the range where it might make a difference whether one got the higher voltage or the lower is below that at which any power transmission, except on the smallest scale, can be carried out. The extent of the danger to life may, therefore, for practical purposes, be said to depend upon the chance of getting a shock, and it will accordingly, perhaps, be useful to put down in tabular form the circumstances under which shocks may be received with the neutral earthed and with the neutral insulated.

It is assumed in this comparison that the earthed neutral system is fitted with releases on all three legs, and the insulated neutral system with releases on two legs, so that a single earth on the lines disconnects the former, whilst to disconnect the latter either two earths are required or a short-circuit between the legs. It is also assumed that the capacity current is not large enough to be dangerous, this being usually the case on mine systems with voltages not exceeding 3,000. Leaks or faults are divided into two classes, one being the ordinary leak to earth, and the other such leaks as those above mentioned, to an accidentally insulated section of a cable sheath, or to a machine frame with disconnected or useless earth wire. This second class of leak, besides being by no means uncommon in mines, is one which there is no easy way of detecting from the surface. In order to save space in the table, this class of fault is called a leak to sheath, though, of course, it includes more than this. The word "terminal" also is used to include live wire. The table is divided into three headings: I., where there is supposed to be no fault; II., where one exists; and III., where there are two.

The table might, of course, be extended, as any number of "sheath leaks" are simultaneously possible without the circuit-breakers opening. It goes, however, far enough for practical purposes.

Of the various accidental contacts made causing deaths the writer has found those described as being between earth and sheath to be far the most frequent underground, whilst those between earth and one terminal have been next in point of number. On the surface those between earth and one terminal have been the most numerous. These have all been with the insulated neutral; that is to say, underground, most accidents have occurred under line 9, next under 3 or 10. On the surface the greatest number have been under 3 or 10.

It is impossible to say how these accidents should have been divided up as between 3 and 10, but of course, on an ordinary

well maintained plant, the time when no leak was on (heading I.) should be the greatest part of the whole; then would come II., with one leak; and then III., with two leaks. It is, therefore, probable that of the accidents classed as under line 3 or 10 there would be more under 3 than under 10.

The reason for the frequency of those under 9 is unquestionably the wide area over which the consequences of the combination of an earth leak and a sheath leak might extend.

Now, out of all the accidental contacts that were made, it is certain that some were made when no leaks existed at all, or where no leaks existed affecting the particular contacts made.

But what would have been the probable results if the neutral had been earthed?

All the fatal contacts on line 9 would have been harmless, for the circuit-breaker would then have cut the circuit out. These fatal contacts depended, of course, actually on there being two faults simultaneously. But a contact between sheath and earth would have been fatal when only one fault existed on a system with earthed neutral (*see* line 5). If, therefore, it is fair to assume that two faults would exist on a system for a smaller fraction of the whole time than one fault, it is clear that more fatalities would have occurred with the earthed than with the insulated neutral. This is, of course, on the supposition that the voltage of transmission is such that its reduction in the ratio of $\sqrt{3}$ to 1 does not make any difference in the proportion between fatalities and contacts, a supposition which seems justifiable in practice.

Similar reasoning applies to the accidents under line 3 of the insulated neutral column, but an extra factor comes in. If the neutral had been earthed these particular accidents would not have occurred, for the circuits would have been interrupted at the time. But similar accidents would have occurred in greater number under line 2; greater, firstly, because heading 1. represents a larger fraction of the running time than heading II.; and, secondly, because there would have been three terminals instead of two to take chances from.

To give a concrete example. Suppose heading I. represents 80 per cent. of the running time, heading II. 15 per cent., and heading III. 5 per cent., that the voltage of transmission was 2,000, and that 50 shocks were received at this voltage in a period of five years with the insulated neutral, under the conditions of line 3. The number of shocks that might be expected to have occurred during the same time with earthed neutral under line 2 would have been $\frac{80}{15} \times \frac{3}{2} \times 50$—*i.e.*, 400; but the voltage received would have been 1,156 instead of 2,000.

If any of the accidents which have been put down under line 3 really occurred under line 10, with the insulated neutral, the same reasoning shows that more would have happened under line 8 with the earthed neutral, as this line only requires one fault, and there would still be those under line 17 to be added to the list with the earthed neutral to get the probable total.

The full comparison of all the lines comes out thus:—

The risks under lines, 1, 6, 7, 13, 15 and 16 are identical under both systems.

Under lines 2, 5, 8, 14 and 17 no danger exists with insulated neutral, but it does with earthed neutral.

To lines 3, 9 and 10 with the insulated neutral correspond the more probable contingencies of lines 2, 5 and 8 respectively with the earthed neutral.

There are left lines 4, 11 and 12 which are impossible with the earthed neutral and dangerous with the insulated neutral. These risks cannot, of course, be sufficient to balance those under lines 2, 4, 8, 14 and 17 with the earthed neutral.

It seems, therefore, that earthing the neutral on a mine is likely to increase largely the number of accidents to life and to add a certain number of interruptions to the service.

Whether these increases would be paid for by the possible reduction of cost of repairing breakdowns seems to the writer highly doubtful. His opinion is that the neutral should not be earthed, that mine cables should be lead-sheathed and armoured, and that no pains should be spared to make sure that such sheathing is kept continuous and in connection with the frames of machines.

The question of safety in the application of electricity to mining depends upon good work, the increase of technical knowledge, and the maintaining of an outlook that is neither hysterical nor brutal.

The Electric Drive in Gold Dredging.—An article in a recent issue of the "Engineering and Mining Journal" states that electric motors and equipment are being extensively used in operating the gold dredging plant at Ruby, Montana. At No. 4 dredge the bucket line consists of 80 buckets of 16 cubic ft. capacity, each bucket weighing about 4 tons. For raising and lowering this bucket line and ladder a 600-ton hoist is placed on the lower deck, inside the house, and is driven by a separate motor of 20 H.P. The motor is of the variable-speed reversible type, and is connected to the drums by a series of reduction gears. The first reduction shaft is fitted with an automatic brake that permits the ladder to be raised, lowered and secured in any position by the manipulation of the motor controller only. This feature is a great improvement in elevator placer-mining dredges. At the present time many dredges are constructed with this hoist connected to the digging motor. The main drive which operates the bucket line consists of heavy steel castings and gearing directly connected to a 300 H.P. induction motor. The main driving gear on this drive is 25 in. diameter, while the main gears are 14 in. diameter and have a 14 in. face. All gears on this drive have cut teeth. The first reduction shaft is equipped with a friction clutch which disengages the motor and acts as a slipping device. The drive complete with the motor weighs 93 tons.

The Gas-tight and Flame-proof Motor Problem.

BY TALBOT DUCKITT.
(Of the General Electric Co.)

Summary.—Attempts have been made to produce motors which are gas-tight and also those which are explosion-proof and flame-tight. The author commences with a description of the totally enclosed type of motor, and the development of the flame-tight machine. He then passes on to discuss water-cooled and pipe ventilated motors. Details of totally enclosed motors, armatures, brush gear and commutators, slip-rings and also of explosion-proof motors are given.

When perusing the report issued by the Electricity in Mines Committee in 1909-10, we cannot help noticing the small number of fatal accidents enumerated in the appendix which have been directly caused by the electric motor. For example, in a period extending over five years, out of a total number of 68 accidents, only two were due to faulty machines. Nor would it appear impossible that even these might have been averted if in the one case more attention had been bestowed upon the motor, and in the other there had been better supervision.

Considering the varied, and in some cases almost impossible conditions which exist underground where motors have to be installed, and the enormous increase in the use of electric power for mining purposes of late years, it is a matter for congratulation that the electric motor has reached this stage of reliability.

Though the conditions are not always such as to require specially designed machines, yet in many cases the ordinary type of motor would be quite unsuitable. This fact has been apparent to manufacturers all along, and from time to time special designs have been brought out to meet the particular requirements when working in dangerous positions. The chief feature in the development of these designs has been the attempt to produce either *a reliable gas-tight motor*, or one which would be *absolutely explosion proof and flame tight*. Even the earliest forms of these designs showed a considerable amount of ingenuity and were so suitable for this class of work that many of the present-day types are practically constructed on the same lines.

The early types of such special motors were all direct-current machines, and it was not until later that the superior alternating-current motor was introduced for mining purposes. These special motors can be classed under the following headings :—

1. *Totally enclosed motors*, popularly known as *gas-tight* motors.
2. *Gauze enclosed motors*, known as the *flame-proof* type.

In addition to these two main divisions there are also many designs where only a part of the motor—*e.g.*, commutators, brush gear, &c.—is made gas-tight or flame-proof.

Before proceeding further it should at once be pointed out that, strictly speaking, it is impossible to make a truly gas-tight motor for practical use, for to be gas-tight the motor case must be absolutely air-tight ; and, even assuming such a machine could be turned out of the workshop, all its gas-tight properties would vanish after it had once been opened for inspection, &c., in a mine. Again, although it may be possible to seal up hermetically certain portions of an electric installation, such as switchgear, &c., it is, however, quite impossible to do so in the case of a motor, for with the latter heating up while running and cooling down again when at rest air will be caused continually to leave and enter the motor shell. This transference will, in a shorter or longer period of time, depending upon the intermittent running of the motor, cause the quality of the atmosphere inside the machine to become exactly similar to that surrounding it. In reality, therefore, the gas-tight machine does not exist, it is merely a name given to a strongly built totally-enclosed motor which may, or may not, be capable of withstanding internal explosions of fire damp.

I.—Totally enclosed Motors.

The first attempts at enclosing motors were made by encasing the ordinary open types in wood, sheet iron or cast-iron boxes ; but later this was improved upon by making the shell of the motor form its own case, the bearings being either made in one with the shell and the combination split in two halves through the horizontal centre line, or the shell being cast in one piece, having facings at each end for bolting on the bearings. Both the latter forms of motor, though not strictly gas-tight—as explained above—are exceedingly useful in wet or dirty situations, and when strongly made form the ideal article for the rough usage generally meted out to them in a coal mine. Some were also made of sufficient strength to be *explosion proof*, so that in the event of gas finding its way into

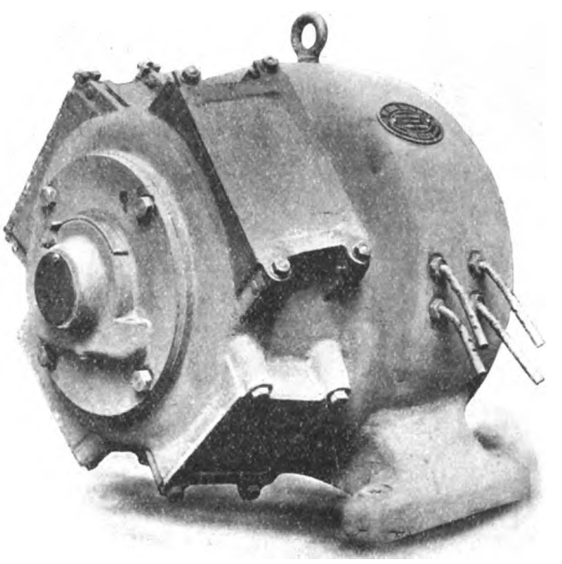

Fig. 1.—General Electric Co's. Gas tight Motor.

the case and exploding no damage resulted to the motor. Unfortunately, such motors have a very serious drawback—viz., the reduced rating for a given size ; for, being totally enclosed, the only means for getting rid of the heat produced in the motor is through radiation from the outside surface. This reduction of output may be as much as 50 per cent. of that given by an open-type machine with the same overall dimensions. Nevertheless, the totally enclosed gas-tight motor is still put forward by many firms, and there is no doubt that for small outputs, positions where space is not a limiting factor, or intermittent running, it is quite a desirable machine. It can always be kept dry and clean inside, and therefore presents the smallest chance of breakdown. This type of machine should always be provided with substantial inspection doors, preferably hinged to the case to prevent them being taken off and not replaced. Experience has proved, however, that these alone are not sufficient ; firstly, because they do not provide for inspection during working, and, secondly, owing to the trouble of removing doors each time, sufficient inspection is seldom given to the motor. Indeed, it has not infrequently

happened that inspection has only taken place when it has become necessary due to an actual breakdown. For this reason gas-tight glass windows should always be provided, these being placed so that the parts requiring inspection can be seen at all times.

Fig. 1 shows a type of direct-current totally enclosed motor for mining work manufactured by the General Electric Co. It is very strongly made, and designed so as to be capable of withstanding an internal explosion of fire-damp without suffering damage. Some makes of totally enclosed motors have numerous ribs cast on the shell, or inspection doors, or both, in order to act as radiators for getting rid of the heat

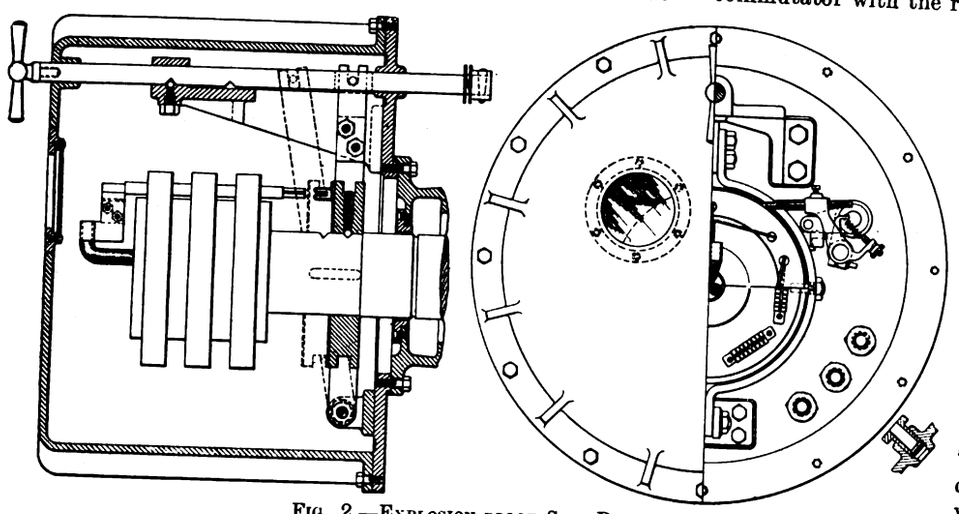

FIG. 2.—EXPLOSION-PROOF SLIP RINGS.

generated inside the motor. These also act as stiffeners for strengthening the shell in case of internal explosions. It is an open question, however, whether the small amount of extra radiation thus obtained will compensate for the increased capacity thus given to the motor for collecting dirt and dust in all the pockets and crevices formed between such ribs. The adoption of ball or roller bearings in conjunction with this type is also desirable, for not only do they reduce the friction loss, but also assist in making a gas-tight job, whilst, further, the very common trouble of oil leakage from the bearings is easily overcome with this arrangement.

Another direct-current gas-tight motor is shown in Fig 7. It has been specially designed for use on coal cutters and is very strongly made, the whole outer case being constructed of steel castings. It will be observed, that to keep the overall height as small as possible, two of the four poles are consequent poles, also that to prevent the field coils from getting damaged through vibration they have been rigidly bolted to the shell. To simplify the problem of making the bearings flame-tight, grease lubrication has been adopted; this at the same time allows the coal cutter to be worked on a gradient without causing oil troubles. The shaft is made exceptionally strong and provided with large thrust collars at the driving end bearing, which is split horizontally to allow of assembling. The motor terminals are inside, and glands are provided through which the connecting cables are taken. At the commutator end two hinged doors are attached, each of which is provided with a strong plate glass window for inspection purposes.

Enclosed Armatures and Brush Gear.—Other devices for totally enclosing have been tried with a view to reducing the available space where gas might accumulate, and an explosion might occur. Thus, instead of making the protecting shield to envelop the whole machine, only the armature, commutator and brush gear may be enclosed, the covers being made to leave minimum clearance between themselves and the armature, and forming a running fit where they surround the shaft at the inside ends of the bearings. This arrangement, though allowing the covers to be of a much lighter structure on account of the reduced force of an explosion, makes it necessary for the brush gear to be very complicated and inaccessible.

Enclosed Commutators.—Another arrangement on the same lines, but intended to minimise still further the cubic capacity of gas liable to explosion, is to encase the commutator only. In this device the brush gear is made in one with the cover, slots being provided for the brushes to pass through. The advantages and defects of this method are the same as those of the enclosed armature, only more pronounced. A reversed commutator with the running face of the segments inside and internal brush gear has also been suggested, and is claimed to have worked very satisfactorily in actual practice. The enclosed vacant space was made so small that it held no more air than an ordinary Davy lamp. Obviously, under these conditions, the motor could only give a small output and be worked at very low voltages.

The chief improvement in mining work in recent years is undoubtedly due to the substitution of *alternating current* for direct current; indeed, so complete is the change that the former has almost ousted the latter from the market in this branch of engineering. This is not to be wondered at when one considers how well adapted in every way is the alternating-current motor for mining work. With it we have all the good qualities for starting and running which can be claimed for the direct-current machine, whilst at the same time we altogether dispense with the chief disadvantage of that type—viz., the commutator. There is no need to make a detailed comparison between the direct-current motor and the three-phase alternating-current motor. For work of this nature the latter is obviously so superior and readily adapts itself to any form of enclosing.

Of course, the squirrel-cage is the nearest approach to the ideal, and this, coupled with the improved method for thoroughly drying and impregnating the coils and insulation, the superior quality of the insulating material now obtainable, together with the absence of any sliding contacts, gives us a machine

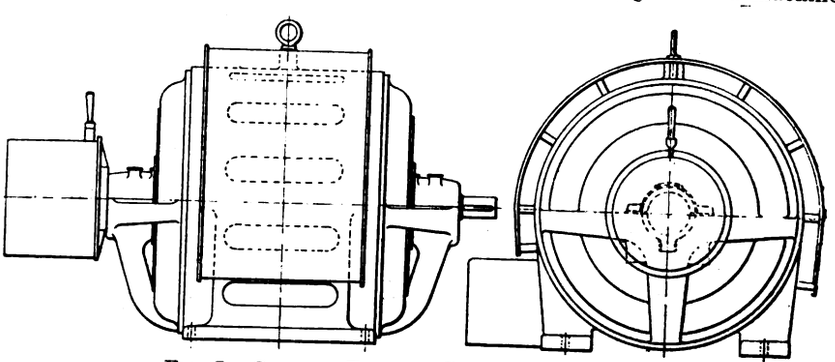

FIG. 3.—GENERAL ELECTRIC CO.'S 315 H.P. MOTOR.

which requires only the minimum amount of attention, so that, in moderately dry and clean positions, this motor is about as reliable as anything that can be desired. Even in positions where the squirrel-cage motor is unsuited to the class of work, and slip-ring motors have to be installed, the alternating-current machine still shows a marked superiority over its direct-current rival, because it is not necessary for the slip rings to be inside the motor, as is the case with the commutator. They can, for example, be placed on an extension of the shaft, outside the bearing, and, if required, be provided with a short-circuiting and brush-lifting device, leaving no sliding contacts

Digitized by Google

to cause trouble while running. The whole slip-ring gear can thus be enclosed in a case of any suitable design, entirely apart from the machine, while the motor proper may be left open like a squirrel-cage motor, with very little risk of causing trouble. Should it be required to enclose both motor and slip rings, this can also be done without having any connection between the two which would allow the air to pass from one chamber to the other.

Fig. 2 shows a set of slip rings with short-circuiting gear and brush-lifting device in a totally-enclosed explosion-proof cover. These were designed by the writer, and are used by the General Electric Co. on some of their alternating-current motors. The drawing explains itself; it need only be mentioned that by the single movement of pulling the handle in a horizontal direction the slip-rings are short-circuited and the brushes raised, and vice versa. For preventing the passage of a flame through the oil channels in the bearing, should any gas accumulate inside the slip-ring cover and get fired, a grooved baffle plate is screwed to the bearing nose, the clearance between this and the shaft being such that, although the gases have a free vent, no flame can pass. Although the chances of explosions taking place inside the slip-ring cover have been found in actual practice to be exceedingly remote, yet at the same time this type of enclosure is very effective as a dust screen, and by constructing them of sufficient strength to withstand the shock of an explosion of fire-damp it also ensures that they are not too fragile for their locality.

The pressure set up in an enclosed chamber by an explosion of fire-damp may be taken to range between 60 lb. and 120 lb. per square inch, though under certain conditions this pressure may be exceeded.

In positions where dripping water is the only objectionable feature to contend against, a very serviceable protection is obtained by attaching to the motor a cover made as shown in Fig. 3. It consists of a No. 14 gauge steel plate, beaded on the edges to give extra stiffness. This is carried far enough down on each side to prevent any possibility of the water getting inside the machine. At the same time it is kept a sufficient distance away from the motor shell, so that the ventilation will not be hampered in any way. A cover so formed takes up very little extra room, while at the same time it is also self-contained with the motor.

It will be thus seen that, with the use of alternating current, open-type motors can be used at their normal ratings, and at the same time the factor of safety in working is greatly improved.

Water-cooled Motors.—The exigencies of mining have produced one evolution of the totally enclosed motor which has done yeoman service in connection with pumping plant, more especially in conjunction with sinking pumps. This particular form is the *water-cooled motor*. It is constructed with a shell having hollow walls, through which either the whole of the water raised by the pump is passed, or else a by-pass from the discharge pipe, or one of the stages when using a turbine pump, is connected to it, and a certain portion of the water pumped is allowed to run through the motor to waste. The first case is only possible with low heads, as otherwise the motor shell would have to be made abnormally strong. In the second case, as the water has a fairly free passage through the motor shell, the pressure in the discharge pipe is not transferred to it. The channels may pass directly through the motor shell from end to end, which is the general arrangement in the former case, or they may be arranged in the form of a spiral to circulate the water round the shell, as is usually done in the latter method. To obtain the best results from this method of cooling it is a good plan so to arrange the internal construction of the motor that the imprisoned air may be kept constantly in motion. By placing suitable channels in the rotor and stator cores, and introducing baffles in other positions, a good circulation can be kept up, which will cause the heated air to impinge on the water-cooled surface of the shell. Should it be impossible to spare the space for such channels, fan blades must be fixed to each end of the rotor, and by this arrangement keep the air in motion.

Fig. 4 is reproduced from a photograph of a 190 H.P. three-phase sinking pump motor which runs at a speed of 1,450 revs. per min., and is constructed on the by-pass cooling principle. The motor is one of a number of this class manufactured by the British Electric Plant Co., Alloa, N.B.

Pipe Ventilated Motors.—Whenever possible, it is a desirable practice to arrange the position of the motors in a mine so that they may be ventilated by intake air. In some cases, to do this, the motor rooms have had air passages connecting them with the downcast shaft, giving very beneficial results. Such a scheme brings before our notice the claim of the *pipe ventilated* motor as a type to be considered as suitable for mining work. Considering the demand there has been since its introduction for installing it in factories where inflammable materials are manufactured, such a claim appears to be quite reasonable. Where, for example, numerous motors are required near the shaft bottom, pipes from the intake airway and the upcast shaft could be connected to them without much difficulty. In many mines this particular locality is not by any means free from dust and moisture, so that the introduction of the pipe ventilated type would provide reliable machines which could not by any chance cause a fire. A motor thus connected would be for all practical purposes gas-tight, and, being gas-tight, explosion-proof, ventilated, flame-tight, and at the same time totally enclosed to keep out dust and moisture.

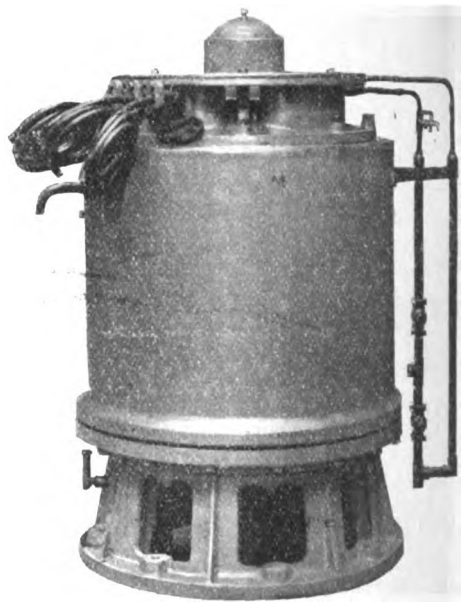

FIG. 4.—B.E.P. THREE-PHASE SINKING-PUMP MOTOR.

The motor is constructed upon the same principle as if it had to act as a heating device—that is, one end of it is connected by means of a pipe or other suitable duct to a source of cool clean air, which is drawn into and through the motor by a fan self-contained with the armature or rotor, and having taken up some of the heat generated in the machine is expelled from the opposite end, either into the atmosphere or through another pipe or duct into a suitable exhausting place.

In designing this motor it is necessary to bear in mind that there are two directions in which the air may be passed through the machine. Thus the air can be taken in either at the commutator or slip-ring end, and out at the driving end, or vice versa. The first is the simpler arrangement, but a drawback presents itself in the cases of direct-current motors and alternating-current motors with the slip-rings inside the shell, for all the dust from the commutator or slip-rings is drawn into the windings. This defect can, however, be overcome by placing the entering orifice so that the air is drawn into the

motor *through* the commutator, instead of over it. When this solution is adopted it is also advisable to resort to ball or roller bearings, as the air current in all probability will cause considerable oil leakage from the ordinary ring lubricated journal bearings.

II.—GAUZE ENCLOSED MOTORS.

The chief claim put forward for this type is its *flame-tight properties*. The gauze enclosed type consists of the addition of fine mesh gauze windows to the totally enclosed examples; these are usually placed in such a position that the commutator and brush gear can be viewed, and at the same time aid the ventilation through the machine as far as possible. The original idea was that the gauze would act in precisely the same way as with a Davy lamp, and allow any gas which percolated through to the inside of the motor and became fired by a spark on the commutator to burn inside or even explode without the flame igniting the gas outside. Thus the flame-proof motor was regarded as an advance on the gas-tight motor.

To show this, experiments have been carried out from time to time with this form of motor by placing them in a chamber containing an explosive atmosphere of air and gas and firing the mixture. It has been claimed that these experiments have, in most cases, shown satisfactory results; but in some, where the burning of the gas has been maintained for any length of time, the gauze has been destroyed. This phenomenon is known as *after burning*. In actual practice the fine gauze has also proved itself to be too fragile and unsuitable a material to deal with, for even if sufficient attention could be bestowed upon it to prevent it from being actually broken, yet it soon becomes silted up with coal dust, and in that state one can realise that it is extremely dangerous instead of being a protection.

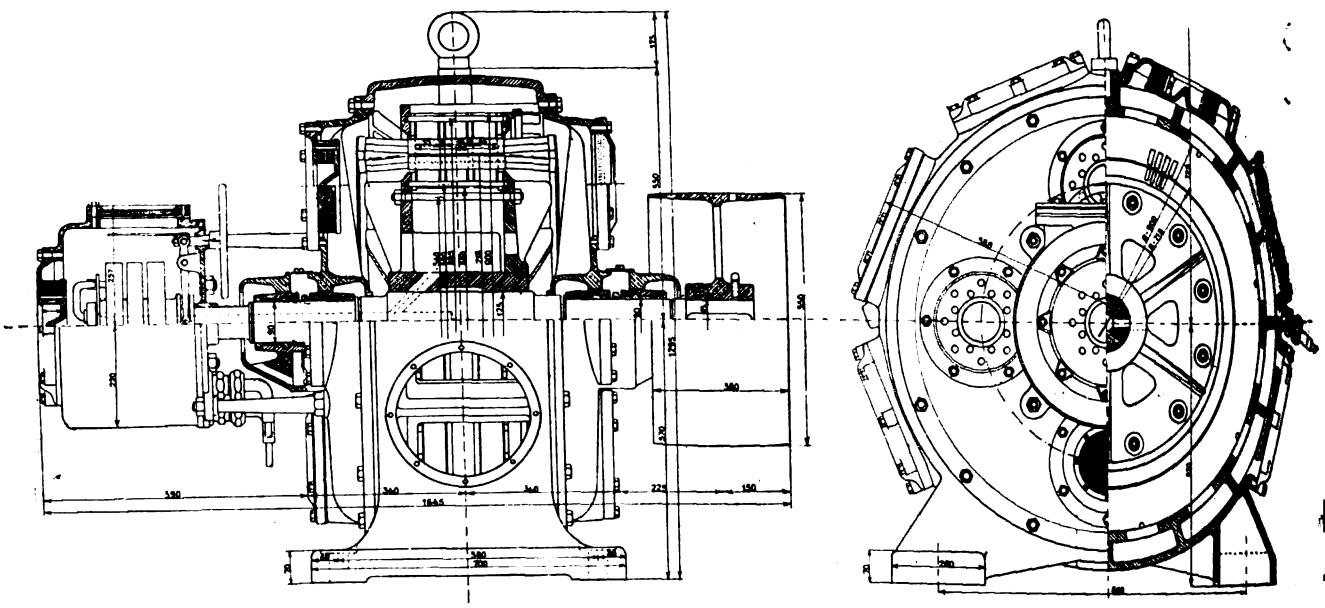
The following data relating to gauze enclosing covers have been derived from the results of tests made with motors in different explosive mixtures of gas. The gauze should be composed of phosphor-bronze wire, about No. 30 standard wire gauge with about 30 meshes per inch. It should on no account be soldered when being made up into covers for attaching to the motor, but secured in place by screwing to perfectly flat machined facings round the apertures, and reinforced round the edges by a sheet metal supporting rim or washer. For protection against external damage it is essential that a stout perforated iron cover should be placed over it, but at a sufficient distance away from the gauze so as not to hinder the ingress and egress of the air. To give a requisite amount of ventilation there should be from 1½ sq. ft. to 2 sq. ft. of gauze surface to every cubic foot of volume inside the motor. As a safeguard against breakage it is advisable that each opening should have at least two layers of gauze. The openings should be numerous and small, as these give better protection against after burning than a few large ones. A fan attached to the armature improves the ventilation considerably by keeping the air inside the motor in motion, but it is detrimental in case of an explosion, as it tends to increase the effect.

Even with the foregoing precautions it is only possible to put any dependence upon the protection thus afforded while the machine is quite new, with every part of it perfectly clean and in good working order.

If, on the other hand, the gauze and the working parts of the motor are allowed to become silted up with dust and oil, the flame-proof properties are no longer the same, and, under certain conditions, such a motor may really be a source of danger.

Owing to the unreliability of gauze as a protection, laminated plate covers or guards have also been adopted.

The latter forms of flame-proof motors have emanated from Germany, where considerable care has been expended in the attempt to get out a realy reliable design. Such a motor is illustrated in the second edition of the "Handbuch der Elektrotechnik," Bd. IX., by Niethammer, from which the following description is taken. The motor was manufactured by the V.E.G. (Vienna), and was put through a series of severe tests at Gelsenkirchen to try its effectiveness when protected alternately with gauze and laminated plate covers. The motor is of the ventilated type and wound for three-phase alternating current. It is provided with slip-rings and short-circuiting device, but not brush lifting. Sections of this machine are shown in Figs. 5 and 6, from which it will be seen that six holes are provided round the periphery of the shell and four holes in each of the two bearing shields for obtaining the necessary ventilation. All the other passages leading from the outside to the inside of the case—viz., the three openings where the cable leads enter and the two where the shaft passes through the bearings—are sealed up. The ventilation holes, both in the shell and bearing shields, have a machined face surrounding them to which the flame-proof covers are screwed. The covers consisting of gauze protection which gave satisfactory results on test are constructed as follows: Three layers of fine bronze wire gauze, 144 meshes to the square centimetre, and made with 0·35 mm. wire, are built up alternately with four separating washers about 5 mm. thick, thus ensuring a space between each layer



FIGS. 5 AND 6.—SECTIONS OF V.E.G. FLAME-PROOF MOTOR.

Digitized by Google

5 mm. On top of this, to protect from external damage, a strong perforated plate, dished to leave a space between itself and the gauze, is placed; the cover thus formed is then riveted together and drilled for the fixing screws. The laminated plate covers are constructed with bronze plates 0·5 mm. thick, the centre portion of which has been stamped out, leaving a washer with a radial breadth of 50 mm. These are built up into packets consisting of 50 plates each for use on the shell openings, and 40 plates each in the case of those on the bearings. Between adjacent plates in each packet separating strips are inserted to make a clearance of 0·5 mm. The packet is then clamped between two strong supporting castings, the whole being riveted together to form a complete cover. The covers are then drilled for fixing screws similar to the gauze ones, and fixed over the openings, as shown on the illustration, where both types of covers can be seen. The three cable lead holes are provided with screwed glands and packing, which grip tightly round the cable and prevent any leakage at these points. The vent holes at the bearings, which necessarily cannot be sealed up, are protected inside the motor by turning grooves in the inside edge of the bearing shroud, where it surrounds the shaft. The shroud is bored 1 mm. larger than the diameter of the shaft, thus leaving only 0·5 mm. clearance space for a flame to pass through. This clearance was found to be a perfectly safe limit. The facings where the covers are screwed on, and also those where the bearings are attached to the shell, are made of ample width and truly machined, so that no possibility of flame leakage will occur at these points. Thus the only channels left are those through the specially constructed protection covers.

On again referring to the illustrations it will be seen that the slip-rings are in a cover which is separated as far as practicable from the machine, so that the effect of an explosion in either chamber cannot be transferred to the other. One passage, however, must remain; this is the hole in the shaft through which the cables pass from the rotor winding to the slip-rings. To close this, soft rubber washers are passed over the cables at the slip-ring end and squeezed together to make an air-tight joint with a cap, which is screwed on to the shaft end.

The cables from the brushes pass through glands similar to those on the motor shell, and where the cover fits round the shaft, protection is provided similar to the grooved baffles adopted on the bearings. Only one ventilator is placed in the slip-ring cover, and this is attached to the outside end. On the top a flat removable cover with a strong plate-glass window is arranged so that the working of the brushes, &c., can be inspected.

The ventilating air that passes through the motor is taken in at the bearing covers and discharged through those in the shell. It is kept in circulation inside by large fan blades attached to the rotor spider to make it as effective as possible. The area of the cover is 81 sq. cm. to every litre of air capacity inside the motor, and it is stated this was 62 per cent. more than was requisite. Although the gauze covers gave perfectly satisfactory results on test, it is claimed that the plate system is superior on account of its greater stability.

One point very noticeable about this machine is that no provision has been made to keep out moisture, consequently it would require extra protection similar to that shown on the open-type motor in Fig. 3. Another query, and a very important one, presents itself to those acquainted with mining work; that is, how long will plates only 0·5 mm. thick, and separated by a maximum distance of 0·5 mm., remain in their original state? Also, what is going to prevent coal dust from caking these crevices up solid, and so turning the motor from a ventilated into a totally enclosed type?

If gas were the only danger to provide against, then there is no doubt that this type of motor would solve the problem. Unfortunately, this is not the case, and it is very questionable whether motors of this class are suitable machines for mining purposes.

We have now practically reviewed every kind of motor put forward for mining work, and it may not be out of place to summarise briefly the general conclusions arrived at. Where there is no risk from gas explosions, then an open-type machine suitably protected against moisture and periodically cleaned to remove the dust is the best solution. Should a possibility of gas have to be guarded against, a strongly totally-enclosed motor, or, where possible, a pipe ventilated motor, should be installed. Where, however, there is a constant danger of explosions from accumulations of gas, then, a *totally* enclosed flame-proof motor actually strong enough to withstand internal explosions without bursting appears to be the only reliable form to adopt. On the other hand, if the conditions are seriously dangerous, then, of course, the question necessarily arises whether considered from all points of view it is not advisable to sacrifice the use of the electric motor altogether.

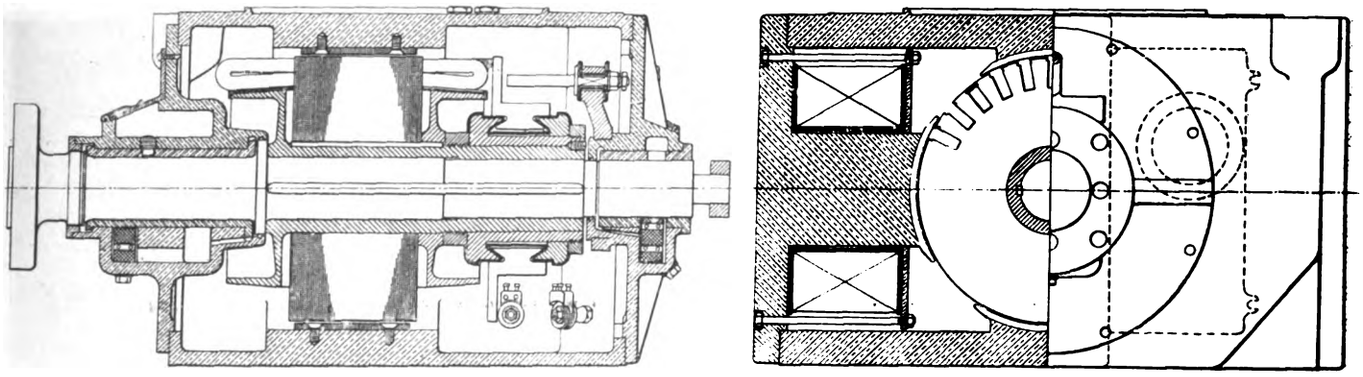


FIG. 7.—GENERAL ELECTRIC CO.'S COAL CUTTER MOTOR.

With respect to the totally enclosed motor, the writer has no experience of a case of one bursting due to an explosion of gas inside it, nor has he been able to trace any record of such an accident taking place. This, of course, may be largely due to the fact that motors are seldom installed in such dangerous positions, but, at the same time, it also confirms the reliability of this type.

With reference to the ventilated flame-proof motor it will be interesting to watch the progress of the special forms, such as the laminated plate protected type now on the market, and to see what amount of extra attention these machines require on account of the more complicated nature of their construction. In any case we may expect further developments to be made with this type of machine.

Looking at the problem as a whole, though it cannot be said all the difficulties have been overcome yet the line of progress has been such as to make us hopeful of a complete solution of the problem before engineering ingenuity is finally exhausted.

The New Electric Mining Rules.

SOME PRACTICAL CONSIDERATIONS.

(FROM A SPECIAL CORRESPONDENT.)

Since the publication of the New Home Office Rules for Electricity in Mines, to which we devoted an editorial article on February 17th, there has been time for considering more in detail some of the technical points raised in the Report. It is especially important to see the more important directions in which the new rules differ from the old rules.

Rule 1.—The old rules, No. 4 (second paragraph), prohibited the use of high-pressure current in parts of mines in which general Rule 8 of the Coal Mines Regulations Act applies, but allowed the use of medium and low-pressure current anywhere; of course, under certain specified safeguards. The revised rules prohibit the use of current in any form "where such use would be dangerous," but allow its use at any desired pressure in properly-constructed apparatus in places where, though not usually dangerous, "open sparking" might cause risk.*

The change is one of form rather than one of substance, for if electricity were used to any extent in dangerous places in mines to-day its accident record could not be so good as it is. On the whole it may be said that the accidents which do occur are, in the main, due to badly constructed apparatus more than to insufficient supervision. The Committee state, page 7, that they "know of no place below ground in which electricity is in use to-day where both kinds of accident would not be avoided if the best present-day practice as regards construction and maintenance were complied with." In the main the effect of this new Rule should not be unduly restrictive.

Various experiments and actual experience over a series of years have shown that if proper automatic cut-out gear whether of the overload or balanced type is installed, and, provided a proper metallic sheath surrounds the cable sufficient to take care of any current due to a fault, especially on the high voltage circuits, the faulty cable is usually cut out before there is actually any open sparking. While the ordinary overload devices have been used in many cases in colliery work, extended experience in Northumberland and Durham has shown that the balanced protective gear, of the Merz-Price type, is really much more suitable for colliery work, because it is a far more certain preventive of overload sparking. The ordinary overload device cannot safely be adjusted with sufficient nicety to cut off the current in case of a fault until it has grown to two or three times the full load current; but in the case of balanced gear the device acts immediately there is a leakage of current of any kind or magnitude, and the faulty circuit is eliminated before there is any serious danger of a big arc. Possibly the best combination of metallic sheaths to ensure this result is provided by a lead sheathed and armoured cable; but the Committee seem to have thought it necessary to provide for alternative methods of construction in view of the prejudice which often, rather unreasonably, exists among some colliery electricians against lead. It is to be noted that if a lead-sheathed and armoured cable is used, protected in accordance with the requirements of the Rules, that is to say, so that the thickness of the lead sheath and armouring respectively are in accordance with the Engineering Standards Committee's recommendation, such cables fulfil the requirements called for by the Rules as to conductivity of the metallic sheath. In cases, however, where a lead sheath is not used, a double armouring may be necessary to comply with the requirements as regards conductivity, and in some cases it would seem that such armouring would have to be thicker than that called for by the Engineering Standards' Committee. It will, therefore, be cheaper in the exceptional cases where double armouring is not sufficient, to increase the thickness of the armouring rather than to provide a special return conductor. Cable makers will, no doubt, be able to give their customers information as to the maximum resistance which can be assumed for the metallic sheaths of their cables. Electricians, however, who need a really first-class job, should give special consideration to the question of lead-sheathed and armoured cables, for such cable, whatever objections may be urged against it, certainly provides a most perfect safeguard against open sparking.

Rules 2 *and* 4.—The notice forms and the notices for workmen have been extended and brought together so that each set of notices forms a separate Rule.

Rule 6 calls for the fire-proof construction of motor rooms and apparatus. Some definition of "inflammable material" is called for. This Rule has been a good deal criticised, but the evidence given before the Committee indicates its desirability.

Rule 8 is more stringent as regards the earthing of motor cases than the old Rule 1c. The requirement that earth plates shall be sunk at the surface for providing an earth connection for the casings of all in-bye apparatus by means of the metallic sheath of the cables, or failing this, by means of a special earthing cable, is new, and has been somewhat criticised on the score of expense. Here again, however, the evidence appears to show that in the opinion of the witnesses it is the only reliable means of securing a good earthing connection for motor cases, &c. The new Rules in general extend the requirements as regards earthing. The earthing of the casings of portable apparatus was not required under the old Rules, but is required for all pressures under the new Rules. One result will be a greater margin of insulation for live parts than some makers of portable apparatus have been in the habit of providing in the past. Colliery managers have been known to complain that when casings are earthed there is more trouble from faults, but it cannot be said to be a common fault.

The Memorandum which accompanies the Report is intended primarily for the information of owners and managers, but one or two of the practical points dealt with therein may be noted; more especially the remarks on the construction of motors (pages 1 and 4); the method of securing an efficient earthing system; the construction of switchgear and cables (pages 5 and 8); and the recommendations as regards the use of low-pressure for all portable apparatus (page 9.)

Pressure.—The limits of low, medium and high pressure as defined in the old Rules are undisturbed in the new ones. The use of high-pressure current is prohibited in motors under 20 H.P. in both codes of Rules, but small transformers of any pressure are allowed under the revised code. Perhaps the most novel suggestion in the Report is the reference to the use of low voltage. Here the Report touches on a development which has not by any means been universally adopted as yet, but which, with the increasing use of alternating current, seems likely to be adopted more and more in the future owing to the various advantages offered. The small wires, lamp-holders and switches used with 250 volts and higher pressures are a nuisance, while the current taken by metal filament lamps, even with voltages as low as 25, are so small as not to add materially to the cost of installation. The Committee's investigation tends to make one believe that there will be a considerable development in the near future in the construction of really suitable transformers of all capacities from one lamp capacity upwards, combined with joint boxes or sealing boxes for tapping the main cables when supplying the lighting at low voltage. In many cases such small transformers may conve-

* "Open sparking" is, we believe, a new term now first introduced, and the definition of which is of interest.

niently be combined with a switch and possibly disconnecting links, either on the high or low-tension sides. The words "switch transformer" proposed by the Committee in their report will probably soon be a recognised term for such apparatus. Such developments should facilitate the construction also of three-phase coal cutters, for the lower the voltage the less the room then taken up by the windings, and therefore the smaller the motor. It is well known that the use of three-phase coal cutters in thin seams has hitherto been a difficulty on account of the large diameter of the three-phase motor compared with a direct-current motor. But this should not prove an insurmountable difficulty to a designer if he can get rid of commutators and high voltage.

In *Rule* 10 (switchgear) an attempt is made to get out general rules which should be complied with in the construction of apparatus used for the controlling the supply of current, but there is purposely no attempt to specify details lest developments should be hampered.

Rule 12 gives the conditions under which armoured cables should be employed, and provides that where mechanical damage is likely protection should be of a substantial nature. This is not always the case with armoured cables at the present time, nor are armoured cables, in practice, always finished off properly at the ends as is provided by sub-section F.

In *Rules* 10 *and* 12 attention is directed to the design of apparatus which can in all circumstances be depended upon to prevent open sparking, and this is dealt with in more detail on pages 5 and 8 of the Memorandum and page 11 of the Report.

While it is not an easy task to provide rules which will provide a proper safeguard to life and at the same time not be irksome to the owner, the new Rules on the whole steer a middle course. Every electrical engineer knows how much more trouble is given by small apparatus than by large, and how much more dangerous it is because of its being more delicate and more easily broken down. With this in mind the Report lays great stress on the importance of low voltages for lighting and for coal cutters, this resulting in a more substantial class of apparatus less likely to go wrong. On the other hand, when it comes to a question of large apparatus or transmission of a large amount of power, the Committee does not hesitate to advocate the use of voltages really suitable for the purpose and which are admittedly safer taking everything into consideration. On these points Mr. Trotter of the Board of Trade gave some useful evidence.

The net result of the new Rules will be to raise the standard of work expected in colliery installations, and to enhance the reputation of electricity in the pit for reliability and absence of trouble.

Public Electric Power Supply to Collieries.

BY W. B. WOODHOUSE, M.I.MIN.E.

(Of the Yorkshire Electric Power Co.)

Summary.—It is shown that a source of public supply has several advantages over a private generating station, among which may be noted the ease with which large motors can be switched on (even winding engines), owing to the large reserve of power, without affecting other plant; the colliery avoids obsolescence of station plant; the capital cost per kilowatt of plant installed in a large station is much less than in a small one, and a larger demand can be supplied per kilowatt installed than is possible in a private station, owing to diversity factor. Consequently the capital charges per unit are much reduced. In regard to generating plant, the author does not look upon exhaust steam turbines with much favour. Finally it is pointed out that there are three ways in which advantage may be taken of a public supply: (1) As the sole source of energy, (2) as a user of surplus power, and (3) as a standby.

The question whether taking a public supply is preferable to generating electricity at a colliery is one which can be answered only when all the conditions of price and circumstance are known in each individual case, but the steady growth of the use of public supply is evidence that there is a large number of cases in which conditions are favourable to purchasing electricity rather than generating it.

At the end of last year (1910) some 140 collieries in various parts of the country were making use of the public supply offered by power companies to the extent of 50,000 H.P., and the number is rapidly growing.

Incidental Advantages.—In a lengthy experience of the use of electricity in mines the writer has been impressed with the great value to a colliery of being able to meet extended demands for power readily and cheaply. It is rarely possible to predict the amount of power which may be required some years ahead, and for this reason many colliery generating stations contain a large number of small and inefficient machines. These for the first few years are very much underloaded, and afterwards, as additions come to be made, the tendency is to instal similar small machines.

One important advantage of public supply is the freedom it allows to users to start or stop large motors without affecting the remainder of the machinery.

Where the generating plant is small the starting of a large motor has a serious effect on the pressure, and sometimes on the engines; usually it can only be done by using expensive starting apparatus. This may be dispensed with where the public supply is used, and in Durham and South Wales examples of winding motors of 1,700 H.P. and 1,000 H.P. respectively are taking a supply from the public mains direct.

The use of electrical winding gears would undoubtedly have spread more rapidly but for the cost of the load equalising arrangements which are necessary; if on a large power system these may be dispensed with, the saving is very considerable, and the necessity to use steam in any form at a colliery disappears.

Obsolescence.—The development in the design of generating machinery has been very great in recent years; that of the steam turbine alone has been so rapid that early machines as compared with those of the present day are quite inefficient and expensive. Gas engine development is also making headway, and the gas turbine is confidently talked of for the future.

The result is that, as compared with electrical apparatus, generating machinery has rapidly become obsolete, and if it be remembered that even now a steam plant only converts 8 per cent. of the heat of the coal into electrical energy, the field for future improvements must be recognised as a very wide one.

As an example of the development that is taking place, a 200 H.P. non-condensing engine of a few years ago required 40 lb. of steam per kilowatt-hour; now a 5,000 kw. turbine* can be bought taking only 14·5 lb. of steam per kilowatt-hour.

On the other hand, 10 years ago cables were as well made as now, and did not differ much in price; electric motors were as efficient, though not as cheap, and the possibility of improving machines having a 90 per cent. efficiency is not great.

Convenience and security are valuable arguments in favour of a public supply, but the question of public supply versus private plant must be decided primarily on the score of cost,

* Recent tests on a 6,250 kw. turbo-alternator at Dunston Power Station, shewed a steam consumption of only 11·8 lbs. per kilowatt hour. (*See* THE ELECTRICIAN, March 10th.)

and as the advantages above mentioned are not of fixed value they must be regarded separately.

A clear understanding of the advantages and disadvantages incidental to public power supply is necessary for one to appreciate how it is that current may be purchased more cheaply than it can be made at a colliery, and to obtain this understanding a consideration of the items which go to make up the cost of energy is necessary.

Cost of Electricity.—The cost of generating electrical energy is made up of—

1. Interest on capital expended on generating plant.
2. Depreciation allowance.
3. Cost of fuel.
4. Cost of wages.
5. Cost of oil, stores, water, &c.
6. Cost of repairs.
7. Proportion of management expenses, rent, rates, &c.

These items occur whether the supply is generated by a colliery company for their own use or by a power company;

FIG. 1A.—COLLIERY LOAD CHART.

but in the latter case an additional charge occurs, namely, the cost of distribution, which must be offset against the advantages incidental to a public supply. In the majority of cases these advantages very largely outweigh the extra cost.

Of the advantages possessed by the public supply the first is the reduced capital cost of generating machinery in large sizes as compared with small sets. Taking average figures, the cost of plant per kilowatt installed in a generating station of 600 kw. will be from 30 to 40 per cent. greater than in a station of 6,000 kw., and twice as great as in a 30,000 kw. station—that is to say, the large station gets twice the capacity of machinery for the same money.

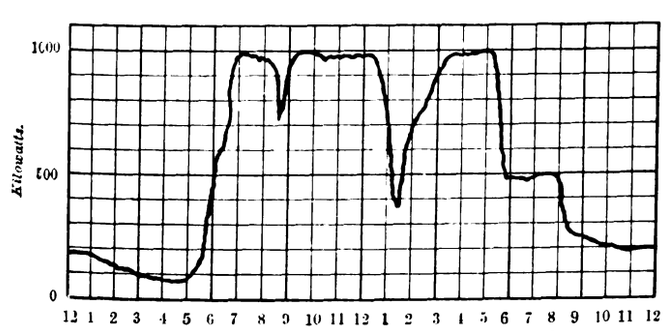

FIG. 1B.—TEXTILE FACTORY LOAD CHART.

The second advantage is the reduction in the amount of spare plant required. In every generating station security calls for one spare generator and boiler at least, whilst economy in first cost and running costs dictates that each machine shall be of as large an output as possible. Therefore in a small station two or three generating sets are usually installed, one being spare; whilst in very large stations the generating plant may be divided into, say, 10 sets without any loss of efficiency. To keep one spare set, therefore, means sacrificing half or one-third of the capacity of the small station and but one-tenth of the large station.

In addition to these advantages possessed by large stations, a power company's supply possesses another, the diversity of its customers' requirements. Each class of power user has characteristic hours of working, fluctuations of load and time of maximum load. For example, collieries, steel works, textile mills, railways and tramways, and town lighting each have different hours of use, and in each case the maximum or peak load occurs at a different hour in the day.

Fig. 1 illustrates this. The characteristic load curves of (A) a colliery, (B) a textile mill, (C) a tramway, and (D) a lighting supply, are each taken as having a maximum demand of 1,000 kw. By the combination of these loads and other industrial loads on one generating station the full benefit of diversity is obtained. In practice it is found that maximum load on a central power station is between one-half and two-thirds of the individual power users' loads added together, the station load is steadier, and its working is more efficient.

Centralisation, then, reduces the proportion of spare plant required for security, and supplies with the same machinery a greater load, and these advantages increase as the power station becomes larger. In the cases considered above, whilst

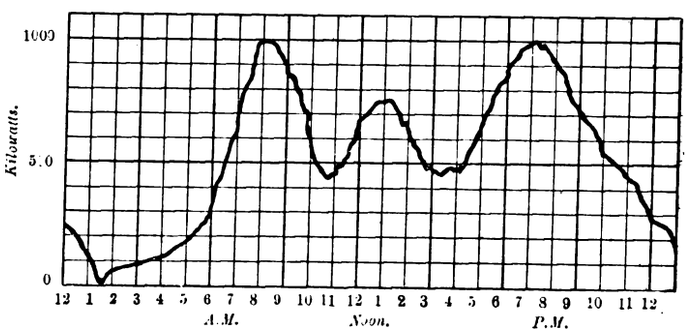

FIG. 1C.—TRACTION LOAD CHART.

the 600 kw. station must keep at least one-third of the machinery spare, the 30,000 kw. station, with one-tenth spare, has a greater margin of safety, as each of the remaining generators is capable of dealing with small overloads sufficient to maintain the full output with one set idle.

Allowing a 10 per cent. overload capacity in each case, and taking the diversity of the load on the large station as being such that the station maximum load is two-thirds of the sum of the consumers' loads (a conservative figure), we have (in the Table below) a comparison of the loads which may be dealt with by each station.

That is to say, for every 100 kw. installed, a demand for

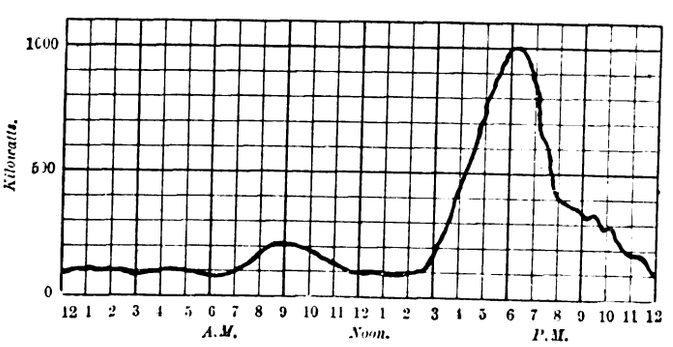

FIG. 1D.—LIGHTING LOAD CHART.

power of 73 kw. can be met by the small station and a demand of 148 by the large station. The proportional cost per kilowatt installed in the two cases may be taken as two to one, and therefore the cost per kilowatt of *demand* for power, which is

Table.

the figure that determines the cost of supply, becomes four to one.

Or, briefly, the central power station possesses three advantages bearing on capital cost :—

1. Large machines are proportionately cheaper.
2. The spare plant necessary for security is a smaller proportion of the whole.
3. The diversity of demand from power users allows a larger supply to be given than if dealt with by separate stations.

The net result is that a central power station can supply a given load with only one-fourth of the capital expenditure that would be necessary on individual stations.

The rapid obsolescence of generating plant has been mentioned, and the necessity to provide for this must be taken into account in both large and small stations ; but the power company, due to the advantages above mentioned, only has to consider the scrapping of machinery, costing one-quarter of the corresponding machinery in a small station, to take advantage of whatever developments in generating machinery may take place.

Of the running costs that of coal is the most important

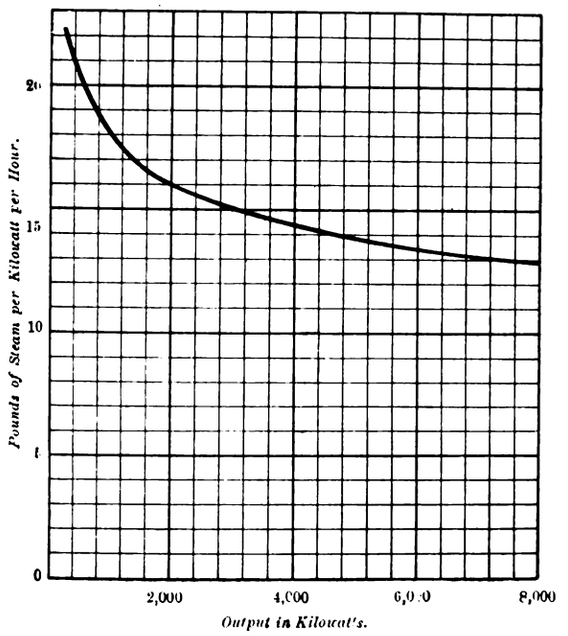

FIG. 2.—FULL LOAD STEAM CONSUMPTION FOR VARIOUS SIZE TURBINE SETS.

individual item ; but undue importance must not be attached to it, as it rarely exceeds one-third of the total charges. This should be borne in mind in considering the advantages of installing new machinery, as the saving in fuel may be outweighed by the annual charges on the capital which must be spent.

The comparative steam consumption of steam turbines of different sizes is shown in Fig. 2. The advantages of large machines are counterbalanced to a greater or lesser extent by the fact that the colliery company have no carriage to pay on the coal they use ; though, of course, its value must be taken as its selling price at the pit, and not at its bare cost.

The amount of coal used to produce a unit of electricity depends on the steam consumption of the engines or turbines ; but a comparison made on the basis of those given in Fig. 2, which compares steam consumptions at full load, would be unreliable unless the very important effect of the steadiness of the load were taken into account.

For every hour a boiler is under steam or an engine is running there is a certain amount of heat energy required to meet the internal losses, quite independent of the load on the machine. That is to say, the amount of coal or steam used per hour may be divided into two parts, one constant, the other varying in strict proportion to the load.

For example, Fig. 3 shows the total steam consumption of a 200 H.P. engine at various loads. A line drawn through the points of full load, half load, &c., cuts the ordinate corresponding to no load at a figure equal to 38 per cent. of the full load consumption. This is the fixed proportion of steam consumption, and it is obvious that if the engine is running on an unsteady load this consumption is a larger part of the total than if the load were steady at full load.

The diversity of demand which occurs in a public supply, in consequence of the reduced maximum load which it brings about, causes the load on the station to be steadier than the individual loads (*see* Figs. 1 and 2), with the result that the coal consumption per unit is decreased.

The value of this extra steadiness of load is very considerable. As a typical example, the coal consumption per unit was taken in a generating station when supplying a variable load, such that the load factor was 22 per cent., and was found to be 5 lb. per unit. By altering the load so that the steadiness was increased to make the load factor 44 per cent. the total number of units generated was doubled with an increase of only 40 per cent. of the coal consumption.

Test figures of coal and steam consumption are, for the reasons indicated above, likely to be an unreliable forecast of actual conditions, and from the writer's experience such figures are frequently doubled under working conditions.

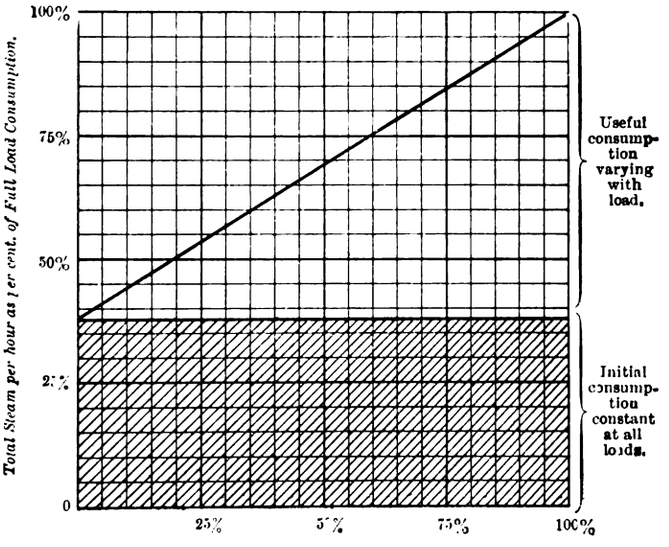

FIG. 3.—LOAD AS PER CENT. OF FULL LOAD.

On all the other items of cost the large station has an advantage over a small one. The labour required to attend to a 5,000 kw. turbine is no greater than that for a 500 kw. machine, and the cost of labour per unit becomes a very small item in a large station. More skilful and continuous attention can also be given to the working of the station without any serious increase of cost.

Exhaust Turbines.—In the last few years much has been heard of the value of the exhaust steam turbine, and wonderful figures of cost have been produced by the simple artifice of neglecting capital charges and the cost of steam, it being argued in defence of the latter omission that as steam is being used which would otherwise go to waste its cost is nothing. This argument, if carried to a logical conclusion, might be made to show that the more wasteful in steam was the winding engine the more power would be obtained for nothing.

It is hardly necessary to say that the exhaust steam turbine, at the best, is an expedient which in many cases would not be adopted if a full consideration had been given to economies in the use of steam in the first instance. The fact that mixed-pressure turbines are now being more generally installed points to an obvious disadvantage of the exhaust steam turbine ; but it has a greater one in its great dependence on a good vacuum for efficiency. An exhaust steam turbine takes practically

Digitized by Google

twice as much steam per unit generated as a high-pressure live steam turbine of the same output.

In the latter case, a difference in vacuum from 28 in. to 23 in. will require an increased steam consumption of 30 per cent. per unit; in the exhaust steam turbine the increase is 50 per cent. That is to say, if the vacuum is good the steam consumption is twice that of a live steam turbine, but on a low vacuum, such as is frequently met with, the steam consumption is three times as great. Where the load is variable matters are still worse. The initial steam consumption of a live steam turbine is 10 per cent., of an exhaust turbine 30 per cent. of the full load consumption; therefore, unless the exhaust turbine is being used to its full output, the utilisation of the steam is even more wastefully carried out than is shown above.

The supply of suitable water for boiler purposes is a serious difficulty at many pits, but the amount of water required for condensing purposes when turbines are used introduces an additional difficulty. Condensing water to the amount of 50 times the turbine's steam consumption is required if a good vacuum is to be ensured (75,000 gallons an hour for a 300 kw. machine), and in the majority of cases it becomes necessary to erect cooling towers to deal with this. Apart from the extra capital cost, the use of such towers requires pumping machinery which under average conditions will absorb 10 per cent. of the

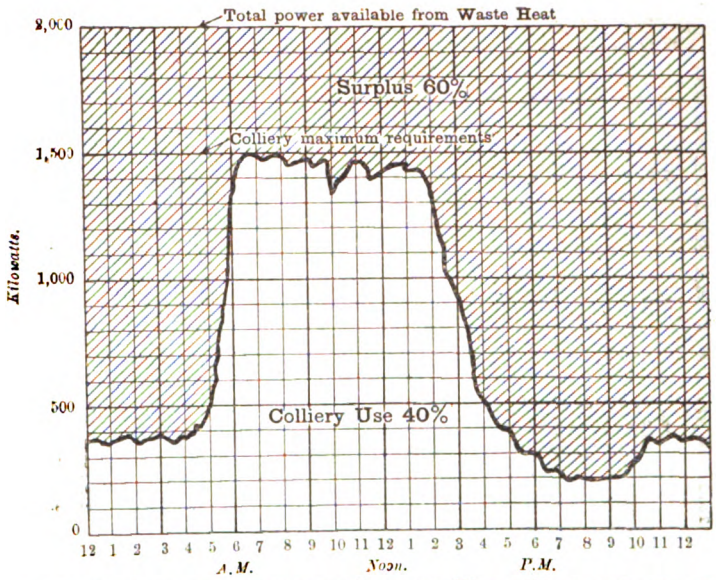

FIG. 4.—SURPLUS POWER FROM COLLIERY WASTE HEAT AVAILABLE BY CO-OPERATION WITH POWER COMPANY.

output of the turbine. The cost and maintenance of auxiliary machinery in connection with exhaust steam turbines are serious drawbacks.

There are, however, some cases in which exhaust steam is available to a sufficient amount to justify its use, but full benefit can only be taken if the use is continuous and steady, and colliery conditions rarely permit this. In such cases, and in those mentioned below, co-operation with a power company offers a satisfactory solution.

Co-operation.—The important effect steadiness of load has on working costs has been mentioned above, and the reasons why the load is steadier on the large supply have been indicated.

The "load factor" (or the proportion the current actually generated in a given time bears to the amount which would have been generated at continuous full load in the same time) of a colliery supply varies very considerably, depending on the use to which the current is put; if current is used for all purposes, including winding, the load factor rarely exceeds 25 per cent. A public power supply station can depend on a load factor of 50 per cent., and the result is a great increase in economy. An increase in the load factor from 15 to 60 per cent. results, of course, in an output four times as great. In a typical case the writer found this increased output obtained with twice the working costs, or the cost per unit was halved, and more productive use was made of the machinery.

Advantage has been taken of this saving by co-operation between power companies and colliery owners, or iron masters, having available a supply of waste heat from engines as exhaust steam, or from coke ovens and blast furnaces as gas. Where waste heat is available continually from coke ovens it may, of course, be made use of by the colliery company to supply their own needs; but in such a case it is necessary to instal spare machinery, and not to depend on the gas to its maximum amount, on account of fluctuations which occur in the supply. The use made will vary during the day, and will be much reduced when the pit is "playing," so that a large portion of the gas is wasted.

Where such fuel is used in co-operation with the power company generating machinery is installed just sufficient to utilise the fuel to its full amount, and it is run at its full load continuously day and night, the current not required by the colliery company being delivered into the power company's mains for use by other consumers. The connection with the power company allows the stand-by to be provided at the company's principal station, and thus full use is made both of capital and fuel.

Fig. 4 illustrates this. The power obtained from the gas is represented by the height of the horizontal line, the power the colliery use by the curved line, the difference in the areas enclosed representing the amount utilised by co-operation which would otherwise have been wasted. A number of stations are in operation on this principle in conjunction with the power companies in Durham, and the results obtained have been beneficial to both parties.

Where a sufficient supply of exhaust steam is available from a winding engine the same principle may be beneficially applied, the colliery company delivering surplus power to the power company when winding is going on and receiving power from the mains at other times, as at night and week-ends. In this case, again, no spare generating plant being necessary, the colliery company's expenditure is considerably reduced.

A third and growing possibility is that of burning low-grade fuel and shale in gas producers and to recover the ammonia, the gas which is generated continuously being supplied to the power company.

To summarise, the public supply can be used in three ways:—

1. As the sole source of supply.
2. As a user of surplus power generated from some source of cheap fuel.
3. As a stand-by.

Whichever use is made of the supply, the general principle remains unaltered—that public supply, like the public supply of water or of transit facilities, is a form of co-operation in which advantage is taken of certain economic conditions to reduce cost.

This principle is often obscured by a consideration of details such as the relative efficiencies of various types of generating machinery; but it is firmly established on sound economic grounds, and the future must see an enormous extension of the use of the public supply.

Hydro-Electric Mining Plant.—The "Mining World" states that the Cleveland Cliffs Iron Co. is adopting electricity as the motive power wherever it is possible to use it in the operation of machinery at its mines on the Marquette range. Power is to be obtained hydraulically, to develop which two centrally located generating stations of large capacity have been erected and equipped, and are in commission; miles of transmission lines have been built and electrical power is conveyed to practically all of the mines operated by the big independent corporation. One of the generating plants will be at Marquette. There is a rapid fall all the way to the shore of Lake Superior, and providing the plans for water storage work out as expected, this one water-power will yield in the neighbourhood of 7,000 H.P. Later on still other streams will be harnessed in a similar manner. The leading officials of the company have devoted much time to personal investigation of water-power development both in Canada and Europe, and they have procured much valuable data.

Power Supply from a Private Plant.

BY W. BOLTON SHAW, M.Sc., A.M.I.E.E.

(Late Electrical Engineer to the Hulton Colliery Co., Ltd.)

Summary.—After considering in a general way the advantages of a private supply as compared with supply from a power company, the author discusses the various types of plant available. Steam plant is generally preferred, and if the installation is above a certain size the steam turbine has distinct advantages. The size of units to be adopted requires careful consideration. Curves are given showing the growth of power at a particular colliery and the relation the consumption bears to the kilowatts of plant installed. Finally, figures of running costs based on actual results are given and the general working of the plant is considered from the point of view of reliability.

In arranging a scheme for the electrification of a colliery, the first point, and one of the most important, to be considered is the question of the generating plant. To the majority of collieries the choice between the alternatives of a private plant or supply from a power company is not open, because as yet no companies' mains are available to them. There are, on the other hand, a large number of collieries, particularly those in the north-eastern counties, which are within reach of a power company's supply, and in their case the relative advantages and disadvantages of supply from a private plant, as compared with a power company's system, require very careful consideration.

Generally speaking, in the case of small collieries, where the ultimate amount of electricity likely to be used is of the order of, say, half a million units per annum, the advantage probably lies with the power company's supply. The figure at which power could be obtained from most companies would be lower than that at which it could be produced by a private plant, and the reliability of the company's supply as regards continuity would in most cases be greater, although this last consideration does not usually carry quite the same weight in the case of a small plant as in that of a large one.

Where there is a probability that at some later date the plant may be considerably extended this probability should be given due consideration in deciding on the source of supply, and if the decision is in favour of the company's supply, it is advisable, if possible, to make such terms as will leave a way clear for changing over to a private plant at the time when the extensions are likely to be proceeded with, since it is quite possible that experience may point to the private supply being then the more advantageous arrangement.

For large collieries, in which an extensive installation is contemplated, with the prospect of an annual consumption of power amounting to, say, two or three million units or more, a careful comparison made between the proposals of a power company and what is possible with a well-designed private generating plant, properly installed and under proper supervision, would, the writer ventures to think, in most cases show the advantage to lie with the private plant.

The main advantage which the colliery possesses over the power company is its ability to produce power at a lower cost. This is largely due to the small commercial value of the fuel used in its boilers, and also to the fact that with the high load factor obtainable the interest and depreciation costs are low. The charge for land occupied is very small; the cost of buildings can be kept low, especially where the colliery has its own brickworks and can erect its buildings with its own staff; the power is generated where it is to be consumed, or within a short distance; and where it has to be transmitted in most cases an overhead line can be erected across the colliery company's own land. The cost of expensive underground mains is, therefore, eliminated; there are no interest charges or heavy legal and Parliamentary expenses to be added to the other items of generating costs, and the management charges are low, since the officials concerned devote only a comparatively small portion of their time to the generating plant.

The generating cost with a plant such as that referred to may be brought down to so low a figure that the difference between it and the price which would be charged by a power company will result in a saving per annum of a thousand pounds or more.

The reliability of a large private plant as regards continuity of supply can be maintained at a level probably as high as that of the mains of most power companies. There is also the possibility, in the event of anything going wrong with the generating plant, of giving some warning of it, and, by being in touch with the trouble, of being able to form a definite idea as to what steps it may be necessary to take in order to cope with the situation created.

In comparing the cost of private generation with the power company's rates account should be taken of the higher cost for the first year or two, while the load on the private plant is being developed. The power company's charge covering this period may be substantially lower, and the difference between it and the private cost must be deducted from the saving in subsequent years. As, however, the total power used during the period is relatively small, the actual difference will in a few years' time be wiped out by the later saving on the private plant. The cost at which it is possible to generate at a colliery is dealt with later.

TYPE OF PLANT.

The installation of a private generating plant having been decided on, the next point to be settled is whether direct or alternating current shall be adopted. For small plants the superiority of one system over the other is not always very definite, but depends largely on the special purposes for which power is to be used and the conditions already existing at the colliery. For large mining installations the three-phase system possesses so many advantages with regard to generating, distributing and operating, as well as safety, that its use may now be looked upon as standard practice in this country.

The type of prime mover to be adopted requires careful consideration, for on its commercial efficiency and reliability the success of the installation mainly depends. Steam plant at present practically holds the field for colliery work, although a number of gas plants have been installed, and more headway appears likely to be made in the near future with this type of plant. The principal, and practically the only, claim of any weight which can be urged in favour of the gas engine in preference to steam is its greater fuel efficiency. As, however, the coal cost for a large steam plant will usually only amount to about one-third or one-fourth of the total cost, a reduction in fuel may easily be counterbalanced by an increase in the interest and depreciation charges, owing to the greater capital expenditure, and in the wages and stores cost on account of the greater expense in operation and maintenance.

The producer and cleansing plant form a further addition to the great variety of apparatus for which the colliery engineer is already responsible, and when these are to be supplemented by a bye-product plant, with the trouble of dealing and finding a market for materials having no commercial relation to coal, it is hardly surprising that the general feeling has been against the introduction of gas plants at collieries.

Another point which places the gas engine at a disadvantage is that the higher fuel efficiency is questionable when commercially considered. Except in very large producer plants the employment of inferior coal, screen pickings and washery settlings, the fuel ordinarily burnt in colliery boilers appears to be impracticable for successful operation of the gas plant, owing to the difficulty of efficiently cleansing the gas.

Improvements in the design of producer plants which will get over this difficulty are to be looked for in the near future, and when their successful operation is assured the gas engine will no doubt stand on a better footing with regard to colliery work than it does at present.

With steam plant the choice lies between slow-speed horizontal engines, high-speed vertical engines and turbines.

For small sets, up to, say, 250 kw. capacity, the type of turbine which at present seems likely to hold its own commercially with the reciprocating engine is the single-wheel impulse turbine; but by far the greater number of small colliery sets are engine driven, the preference being about equally divided between horizontal and vertical.

There is no doubt that the horizontal slide-valve engine commends itself to the average engineer at a small colliery, because of its cheapness and simplicity, and, being of the same type as his winding and other engines, it fits in well with the general scheme of things. It can be run by almost any sort of handy man, and ordinary repairs to it can be carried out by the type of fitter accustomed only to colliery work. The fact that it will continue to run even when in serious need of overhauling is often taken advantage of to keep down the cost of repairs, and generally results in an enormous waste of steam.

A pair of 120 I.H.P. engines of this class, tested by the writer some years ago in their ordinary working condition with 80 lb. steam pressure and running non-condensing, showed a full load consumption of 60 lb. per kilowatt-hour for one engine and 69 lb. for the other. The no-load consumption was not very much less than that at half load.

The horizontal engine requires very heavy foundations and large engine room space. This space can be somewhat reduced by a reversed drive—*i.e.*, by placing the generator behind the cylinder—but such an arrangement exposes the generator to the risk of serious damage should the cylinder cover be knocked off or the cross-head or connecting rod break. Small high-class horizontal engines of the Corliss compound or Stumpf type give lower steam consumptions than high-speed engines or turbines, but the cost of engine is considerably higher. The heavy cost, large foundations and great amount of floor space required practically put them out of court for a large colliery installation. A rope or belt drive, though always objectionable, is usually adopted owing to the very much greater cost of the slow speed generator required for direct coupling.

Advantages of the Steam Turbine.

With the tendency to greater efficiency and a higher standard of engineering which is now observable at a great many of our collieries, the adoption of high-speed engines or turbines in preference to horizontal slide-valve engines is likely to become more general. The high-speed engine-driven set has the advantage of occupying, in the smaller sizes at any rate, even less floor space than the turbine, but it loses to some extent the advantage due to its small floor space by requiring greater head room than either the turbine or horizontal engine, and where provision is made for lifting, as it should be, the cost of the engine room is appreciably increased by the greater height required. The foundations are smaller than those for a horizontal engine, and the efficiency is more likely to be maintained for a longer period, one reason for this being that, owing to the high speed of reciprocation, the engine soon calls attention to any wear that has taken place in the moving parts.

For small plants the turbine does not show up to the same advantage compared with the engine as in large plants. Its cost below a certain size is higher; it is questionable whether its consumption is any better than a high-class engine, taking into account the power required for condensing and cooling; and in the present state of engineering knowledge existing at small collieries there is no doubt that the man responsible for it requires to be of a somewhat higher grade than for the reciprocating engine. It is not so much that the turbine is a more intricate machine or more difficult to understand than the engine—it is in many respects simpler; but the engine is a common object of the colliery or any other industrial works, while the turbine is as yet a long way from being so, and thus almost every man who has had any mechanical training at all is more or less familiar with the engine, while the same can be said of comparatively few men with regard to the turbine. The rapidly increasing number of turbines installed in this country is, however, bringing about a change, and the last five years have shown a remarkable spread in the general knowledge of turbine engineering.

Notwithstanding these disadvantages, there are, no doubt, many small installations having sets of, say, 150 kw. and upwards, where turbines could be shown to be the best type of prime mover taking all the conditions into consideration. For larger installations the turbine has many advantages over the engine, advantages so generally recognised that for sizes over 500 kw. it is becoming almost standard practice. From 300 kw. to 500 kw. the high-speed engine is still able to give a good account of itself; but it is probable that as confidence in the turbine grows with improved design on the part of the manufacturer and increased knowledge on the part of the colliery manager and engineer, the size of set for which engines and turbines stand on an equal footing will tend to become considerably smaller than at present.

The special features of the turbine which make it particularly suitable for colliery installations are the low capital cost of turbine and generator, as well as of engine house and foundations, low steam consumption, small wages cost for operating and small maintenance cost for stores and repairs. Against these must be set off the somewhat higher cost of condensing and cooling plant as compared with reciprocating sets.

The simplicity and reliability of the turbine when operating either singly or in parallel, its ability when once run up to take care of itself automatically, and its immunity from damage under heavy overloads tend to reduce the amount of attention necessary and so keep down the cost of engine-room wages.

The small floor space occupied makes possible a very compact lay-out of the engine room, so that the driver is always within easy access of any set. Added to this, the small height of the machines enables him to have the whole of the plant under observation from almost any part of the engine room, so that the amount of plant which can be controlled by one driver is brought to a maximum. With turbines it is possible to have the engine room arranged on a girder and concrete floor some 12 ft. or 15 ft. above ground level, and to place the condensing plant on the floor level below. The unoccupied portion of the ground floor, which will probably amount to half or more, can be made use of as a workshop, and is in many ways a convenient arrangement, one special advantage being that the foreman or electrician-in-charge, as well as the principal workmen, being located there, the power house is always more or less under supervision, and in case of anything going wrong there is someone at hand to give assistance at once if required. Where the power house is run by a single driver this is particularly advantageous.

Another feature of the turbine, and one of particular importance in colliery work, is its ability to make use of exhaust steam and to run on live steam when no exhaust steam is available. Roughly speaking, the amount of steam exhausted from the winding engines of a group of pits is generally sufficient to generate enough electricity for the complete electrification of all machinery above and below ground except the winding engines at that group of pits. By installing mixed-pressure turbines a large amount of fuel can be saved during working hours, but it should be kept in mind in estimating the effect on the generating costs that against the saving in fuel must be set the increased capital charges on the accumulator, low-pressure steam piping, more expensive turbine and larger condensing and cooling plant, these latter also requiring more power for pumping.

There is also to be taken into account the somewhat higher consumption of the mixed-pressure turbine when running on live steam as compared with what would be obtained with an ordinary high-pressure turbine, and a still more important consideration is the increased steam consumption of the winding engines which may result from the back pressure put on them by the friction of the exhaust pipe line and head of water in the accumulator, added to the working pressure of the accumulator itself.

Size of Units.

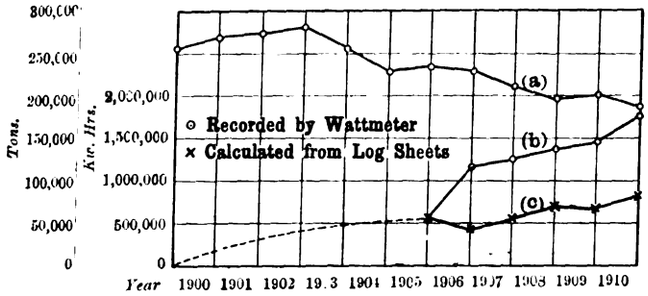
Having decided on the type of generating set, the next point to be settled is the size of unit to be adopted. The best policy

Digitized by Google

is to adopt such a size that subsequent extensions to meet increasing load requirements can be made by the addition of sets of similar size.

Special circumstances or requirements may afterwards render it advisable to depart from this scheme, but adherence to it will give uniformity in the lay-out and design of the power house and in many details of the plant, including steam and water pipe work, condenser and cooling pumps, cooling plant, switchboard panels, &c., as well as simplifying the arrangements for stand-by plant.

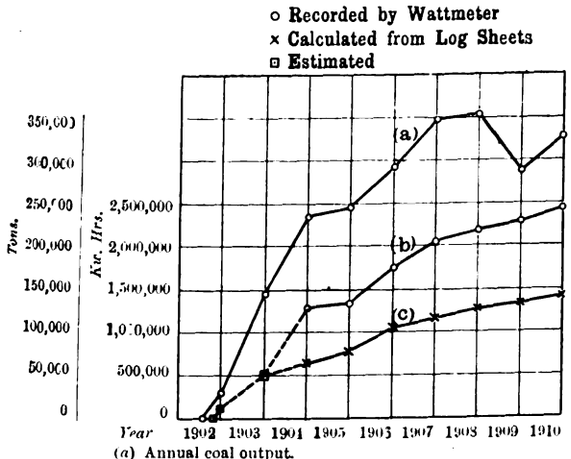
One determining factor in settling the size of units should be the provision of sufficient capacity that, from a careful con-



(*a*) Annual coal output.
(*b*) Annual electrical output including power for fans.
(*c*) Annual electrical output excluding power for fans.

FIG. 1.—ANNUAL OUTPUT, "A" PITS.

sideration of the probable rate of growth of the load, it does not appear likely that any additional unit will require to be put down within a period of less than four or five years. Otherwise the power house hardly recovers from the state of disorder produced by the extension before it is again in a state of upheaval. The size of unit should also be determined by the size of the manufacturers' standards. Special sizes can be obtained from some makers without much difficulty, but, unless there are very special reasons for not doing so, much is to be gained by keeping to the makers' standards. Some consideration should also be given to the fact that in the early years, before it becomes necessary to run the second set, the first set will have to run for a considerable portion of the time on small loads, and the steam consumption on such loads will be higher the



(*a*) Annual coal output.
(*b*) Annual electrical output including power for fans.
(*c*) Annual electrical output excluding power for fans.

FIG. 2.—ANNUAL OUTPUT, "B" PITS.

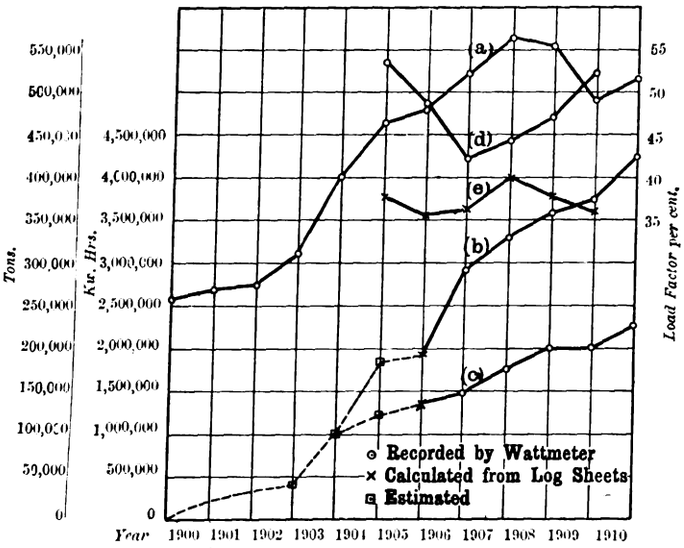
larger the set. The difference, however, between one set and the next standard size, when run on small loads, even for long periods, would be hardly appreciable in the fire hole. In addition to this, the consumption after the second set is required—*i.e.*, with loads above half-load, would be lower for the larger size of unit, and any extra fuel burnt on account of the large unit in the early years would no doubt be more than made up for afterwards.

Standby plant is, of course, an absolute necessity, and there will, therefore, always be one set in excess of the number necessary to deal with the load. Looking ahead as far as possible, say for 10 years, and estimating the size of the plant required then, a consideration of prices of different sized sets will show that there is one size, or possibly two, for which the necessary equipment, together with a spare set, will cost the least money. In making this estimate, the cost of the condensers and auxiliaries must be taken into account. Due consideration of these various factors will enable a suitable size to be decided on, which will most nearly meet all the conditions.

ESTIMATES OF POWER.

An estimate of the power requirements over a considerable period is a somewhat difficult matter to arrive at, and even for the first year or two it is quite possible for the estimate to be considerably out. The most satisfactory way of making an estimate is to obtain figures giving the annual electrical consumption of other collieries having similar installations to that proposed, and to make what deductions or additions appear necessary for obvious differences in the equipments. With so many collieries now electrically equipped it should not be difficult to obtain these figures.

The curves given in Figs. 1 and 2 show the consumption of electrical power at two groups of pits, distinguished as A and B pits, at a colliery having a large electrical installation.



(*a*) Annual coal output.
(*b*) Annual electrical output including power for fans.
(*c*) Annual electrical output excluding power for fans.
(*d*) Load factor including power for fans.
(*e*) Load factor excluding power for fans.

FIG. 3.—TOTAL ANNUAL OUTPUT, "A" AND "B" PITS.

The corresponding coal output for each group of pits is shown on the top curve (*a*). At the A pits the use of electricity dates back to the year 1900, and it will be noticed that the output of coal had then nearly reached its maximum. The electrification of these pits was only partial, and was more or less gradually developed. The B pits were, with the exception of the winding engines, completely equipped electrically from the first, and the supply commenced with the winding of coal.

At both groups of pits the ventilating fans were eventually changed over to the electrical drive, and it will be seen that a considerable portion of the power consumed was absorbed by these motors. As motor-driven fans would not be included in the electrification scheme of some collieries, and as their influence on the load is very considerable, the curves (*c*) have been drawn showing the output to the rest of the installation apart from the fans. It will be noticed with regard to curves (*c*) that both for the completely and for the partially equipped pits, the electrical output tends to reach a steady value when the coal output of the pits has passed its maximum.

Fig. 3 shows similar curves for the combined output of the two groups of pits. It should be mentioned that in 1906 the generating plant at the A pits was shut down, and the whole of the supply concentrated at the B pits. Curve (*b*) in Fig. 3 may

be taken as representative of a large colliery installation, and curve (*c*) in Fig. 1 of a small one.

The growth of the load is dependent on three principal factors :—

1. The period occupied in changing over to electrical driving from steam. This may possibly amount to five years or more before the change is complete, and its progress will depend largely on the confidence of the management in proceeding with the electrification, and also on whether the state of the coal trade justifies the necessary expenditure.

2. The natural increase in the power required by the increased get of coal, if the mines are comparatively new at the time of electrification.

3. The effect of the workings getting further in. This increases the power taken for haulage, ventilation, and possibly also for pumping. With longer roads the work done in haulage per ton raised is naturally greater, and, in addition, if the seam is on the dip with the main roads level, the coal on the higher side is usually taken out first. All haulage of this coal to the main road is gravitational, and no power is therefore required except along the level. Later the coal faces on the lower side are developed, and power is required for hauling up the brows, the amount increasing with increased output from these lower faces and also with the greater length of brow as the faces are advanced down the dip.

With the opening out of more roads and districts more air is required for ventilating the mine, and as the roads lengthen out their resistance is increased, so that, as time goes on, both the quantity and water gauge of the fan are increased, and with them the demand for power to drive the fan.

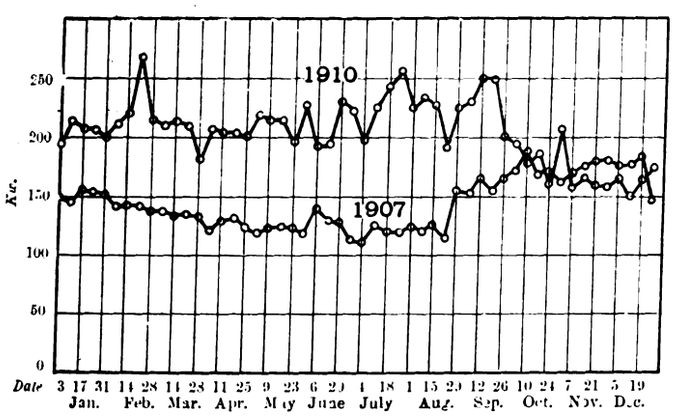

FIG. 4.—WEEKLY AVERAGE LOADS OF "A" PITS FOR YEARS 1907 AND 1910.

If much water is made in the mine the opening out of the lower faces tends to increase the quantity, or, if not to increase it, to cause it to be made at a lower point, and thus require to be pumped against a greater head, with a corresponding increase in the power taken by the pump.

As a mine passes the zenith of its working life the output of coal begins to fall off, but the workings get further in, and the net result is that the consumption of power tends to remain stationary, or even to go on slightly increasing until the mine is very near to finishing, and only then is the consumption likely to fall off seriously. In the meantime the output of coal from other mines is increased to compensate for this falling off in order to keep up the supply of coal to the market. The tendency is, therefore, for the power consumption to keep on increasing until the total coal output of the whole colliery begins seriously to fall off—that is, until the life of the colliery is coming to an end.

In estimating the amount of power likely to be required at a colliery contemplating electrification, the general tendency is to over-estimate the amount in the initial years and to under-estimate it for the later ones. The first is a fault at any rate in the right direction, but the second may result in a good deal of unnecessary expense and inconvenience, owing to sufficient allowance not having been made for subsequent extensions to buildings, boilers, pipework, cooling plant, &c.

Having arrived at an estimate covering as long a period as it is possible to forecast, the corresponding curve of average load can be obtained for each year by a process of simple arithmetic. It is necessary, however, in fixing the size of the generators to determine the maximum load to be carried, and this will depend on the load factor to be expected.

The load factor for any year is usually defined as the ratio of average load, taken over the whole year, to the maximum load on the generators at any time during the year. The term, however, is somewhat indefinite, because of the difficulty of deciding on the method of determining the maximum. A mere momentary overload can hardly be regarded as a maximum to be seriously considered, because the expectation of it would have no effect in deciding on the capacity of the plant to be run. The question then arises how long must a temporary overload persist to be seriously considered as a maximum. In the curves (*d*) and (*e*) shown in Fig. 3 the maximum is taken as the highest hourly reading recorded on the power-house log sheets. As a heavy overload coming on momentarily or for a period of a few minutes only would divert the attention of the driver from taking his readings to looking after his volts, such an overload would not be recorded amongst the ordinary readings. It may be taken, therefore, that these readings are of sustained working loads, existing perhaps for a quarter or half an hour or even more, and are such as must be taken into account in determining the capacity of plant to be run.

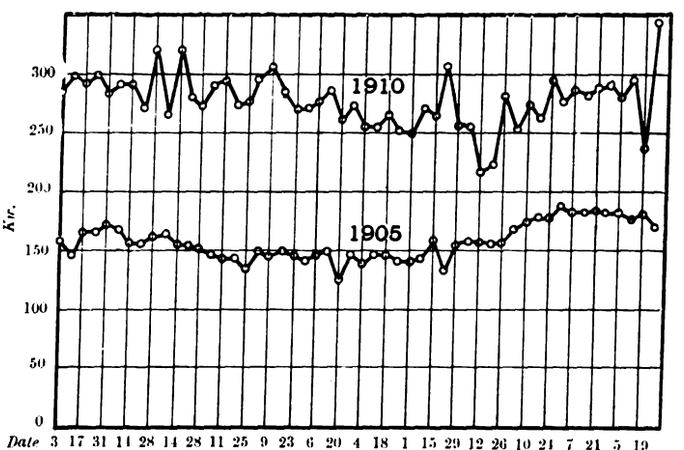

FIG. 5.—WEEKLY AVERAGE LOAD OF "B" PITS FOR 1905 AND 1910.

Curve (*d*), Fig. 3, shows the load factor for the combined load of A and B pits, with power for ventilating included; curve (*e*) shows the same with ventilation excluded. It will be seen that, as might be expected, the load factor is very considerably improved by the addition of the fan load. The somewhat large drop in (*d*) in 1906 is due to the installation of a large stand-by fan which was only run up occasionally, and thus added considerably to the maximum load without having much effect on the average load. In later years the power taken by this fan has been reduced and the period during which it is run increased, so that its effect on the load factor has gradually become less prejudicial. For large installations with electrically-driven fans or other important continuously running plant probably 40 to 60 per cent. would be safe limits within which to take the load factor, and for one without continuously running plant from 30 to 45 per cent. For small installations 25 to 35 per cent. is probably as good a figure as can be expected.

Taking curve (*b*) in Fig. 2, the output at the end of 1906—*i.e.*, after four years' working—is 1·75 million units, giving an average load of 200 kw. Assuming a load factor of 48 per cent. (the average of curve (*d*), Fig. 3), the maximum load would be 415 kw., and for this installation the choice of generating plant would probably lie between 350 kw. and 500 kw., as the nearest standard sizes.

It may be urged that the maximum load might be taken care of by the overload capacity of the plant, but it should be borne

Digitized by Google

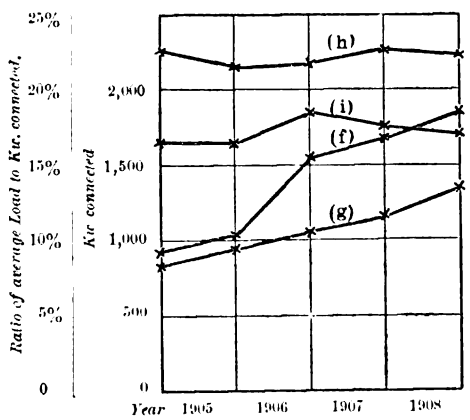
in mind that the maximum load recorded may be sustained for an hour or two, and may only be some 5 or 10 per cent. in excess of the load preceding and succeeding it for several hours. Generally speaking, it is advisable to make it a rule always to have sufficient plant running to keep the working load, under all ordinary conditions, within the rated capacity of the generators, and only take advantage of the overload capacity to deal with sudden peak loads and cases of emergency. By insisting on this rule being observed there is an avoidance of the risk entailed in the driver using his own judgment as to how long it is safe to run on any particular overload.

The maximum load may generally be expected in midwinter, when the output of coal is greatest and the lighting load is heaviest. It usually occurs in the early morning after work has got into full swing, and before the surface lights have begun to go off.

Where two day shifts are worked, under the Eight Hours Act, a second maximum may occur late on in the afternoon, after the lighting comes on again and before the workshop and other machinery which only runs one shift has gone off.

Figs. 4 and 5 give curves showing the average load plotted weekly over the whole year for pits A and B respectively. In each case two curves are given showing different years. It will be seen that the tendency of the load is to fall off somewhat in the summer months.

A method by which the probable load might be checked to some extent is by making an estimate of the total rated capacity of motors and lights likely to be connected up and taking the average load as a certain proportion of this.



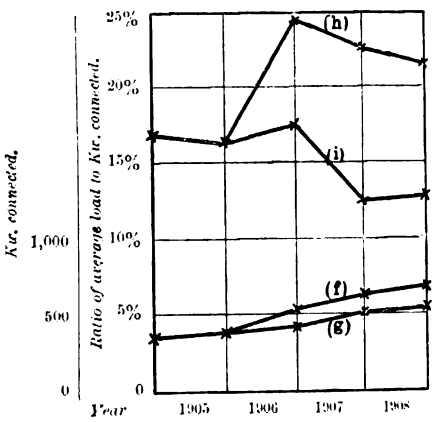
(*f*) Total connections including fan motors.
(*g*) Total connections not including fan motors.
(*h*) Ratio of average load to connections including fan motors.
(*i*) Ratio of average load to connections not including fan motors.

FIG. 6.—TOTAL CONNECTIONS AND AVERAGE LOAD "A" AND "B" PITS.

It will be seen from the curves (*f*) and (*g*) shown in Fig. 6 that the ratio between these two quantities, taken for A and B pits combined, is practically constant over a period during which the total kilowatts of motors and lights increased 100 per cent., as shown by curves (*f*) and (*g*). Without the fan motors the ratio is naturally smaller, but still remains practically constant. Including fans it averages 22·1 per cent., and excluding them 17·1 per cent. Taking the two groups of pits individually, the value of the ratio is more variable, especially for A pits. Curves of these values are shown in Figs. 7 and 8; the average, including fans, over the same five years is 20·5 per cent. and 23·1 per cent. for A and B pits respectively; and without the fans 15·3 and 18·6 per cent.

Probably a safe figure to take would be from 15 to 25 per cent., according to the size and character of the installation, the proportion of continuously running plant, if any, and whether the motors carry loads reasonably near to their rated full-load capacity. In the pits referred to, especially at the B pits, care has always been taken to avoid putting in motors with too large a margin of capacity over their working load. As showing how consistently this policy has been adhered to, it may be mentioned that the power factor on the generators has been maintained at an average of over 0·84 per cent. for the last seven years, and the lowest value obtained was 0·825 in the earlier part of that period.

For small installations and for the immediate requirements of large ones a rough estimate of the probable load to be carried by the generator may be made by taking the total load on all the motors and lights likely to be working at the same time of the day when work is at full swing and multiply this total by a "diversity factor." Where there are a large number of intermittently working motors, as, for instances, those driving haulages, screens, saw benches, coal



(*f*) Total connections including fan motors.

FIG. 7.—TOTAL CONNECTIONS AND AVERAGE LOAD. "A" PITS.

cutters, &c., the natural tendency is for the individual loads to dovetail into one another, and so give a smaller total than their sum. The value of the diversity factor will depend on the relative horse-powers of the steadily loaded motors and of those intermittently loaded. A value between 60 and 80 per cent. would probably be obtained on an average installation with, say, 20 or more motors.

It is not proposed here to go into a detailed consideration of the merits and suitability for colliery work of different types of boilers, condensing and cooling plant, switch-

boards and other items which go to make up the complete generating plant. It may, however, be said that in deciding on the type of plant to be installed, special consideration should be given to those features which make for simplicity and reliability. Preference should be given to plant which is simple in design and method of working, so that the man who operates it may not require to possess a high degree of skill or technical

knowledge; and, further, the plant should require as little attention as possible in the way of cleaning and overhauling. The absence of parts which wear or corrode is an important consideration.

In the general lay-out and design of the plant as a whole special attention should be given to "directness." By this is meant the avoidance of arrangements which lead to confusion and serious mistakes, and the placing of accessories and apparatus so that, as far as possible, their interconnection is obvious. The aim should always be so to lay out the plant that the man operating it is within easy reach, and with as little moving about as possible, within sight of all the levers, hand wheels, instruments, gauges, &c., which affect the operating of the machines or indicate their normal or abnormal working.

Attention to details of this sort makes for increased efficiency of the men, reduced risk of breakdowns and stoppages, and a minimum loss of time in dealing with the latter when they do occur. For simplicity's sake it is advisable to make each unit self-contained as far as possible, each set having its own exciter, steam separator, condenser and condenser pumps. The pumps for the cooling plant should also for this reason be in sets each of sufficient capacity to deal with the water from one condenser. The generator and exciter panels of each set should be so arranged relatively as to form one unit easily distinguished from the next one to it, and should be so placed and labelled that their connection with the generator to which they belong is conspicuous and unmistakable.

Cost of Generation.

The main items in the cost of generating are interest and depreciation and coal. In addition to these there are the charges for wages, stores and replaces, as well as for management, rent, rates, insurance, &c. The figures for generating costs sometimes put forward as having been obtained at collieries should be accepted with a certain amount of reserve. Unless great care is observed in keeping the costs it is extremely easy, where both labour and materials for general purposes are so plentiful, for quite considerable items to be omitted from the cost of generating and charged to the general colliery or mine costs. These items may be quite large enough to appreciably affect the generating costs if correctly charged and yet be unnoticed in the much larger general costs.

The question of capital cost also requires some consideration as to where the line is to be drawn between it and maintenance. Generally speaking, any work carried out in addition to the actual installation of the plant, if in the nature of alteration or extension with a view to improving the working of the plant or obviating some defect, should be regarded as capital expenditure, while the replacing of parts worn out by ordinary wear and tear or damaged through breakdown, as well as the work of periodically overhauling and cleaning, should be charged to those items which go to make up the maintenance cost.

Large items of what are strictly speaking repair or maintenance work, such as the re-lining or re-boring of engine cylinders, the complete re-blading of a turbine or the re-winding of an armature rendered necessary as the result of deterioration from continued service, may reasonably be charged to capital account, especially when the depreciation charges are based on a period shorter than the average life of the machinery concerned.

The question as to what rates should be charged for interest and depreciation on the capital expended on generating plant is one which could be discussed at considerable length; but the amounts now usually accepted—namely, 5 and 10 per cent. respectively—probably represent a fair figure for most collieries. Five per cent. is a small rate of interest compared with what is being earned on the capital of some collieries; but it should be borne in mind that the nominal capital of a colliery undertaking often does not represent anything like the amount of expenditure which in other concerns would be charged to capital. In the development of new mines much of the money spent in sinking, opening out and equipment may be provided by the sale of coal raised in the early period of working. It may also be objected that the figure taken for depreciation (10 per cent.) is somewhat high, having regard to the life of such plant as boilers, turbines, high-class engines, generators, switchboards, centrifugal pumps, pipe work, buildings, reservoirs, &c. The life of a colliery or group of pits should, however, be the determining factor, and 20 years is probably a fair average to take for this. When the colliery is finished the plant will have little more than scrap value, even if in good condition, and it is therefore advisable that all capital expenditure should by then be paid off by depreciation. As the capital will almost certainly continue to be expended on extensions to the plant up to, and probably beyond, the end of the first half of the colliery's life, it will be admitted that 10 per cent. is not an unreasonable figure.

The cost of coal is also a matter somewhat difficult to determine accurately owing to the indefinite commercial value of the fuel usually burnt in the boiler fire hole. At some collieries, where there is absolutely no sale for this class of fuel, its value can only be calculated by the cost of handling it on the surface and the amount of money which would be saved in underground costs if it were not brought to the surface. Under these conditions values varying from 2s. to 3s. 6d. have been estimated. On the other hand, there are collieries at which small amounts of inferior coal can actually be sold at prices possibly as high as 5s. or 6s. per ton, and at these collieries the coal burnt in the boilers would be charged at the same rate. The charging of the full market value is, however, open to some objection on the score that the placing on the market of considerable quantities of this low-grade fuel might create a demand which would affect detrimentally the prices obtained for the higher grades.

The table on p. 63 shows a series of annual generating costs extending over a period of 11 years for a large colliery with an output increasing uniformly to a maximum of 5 million units in 10 years' time. The figures are based on actual working costs obtained in connection with the central generating plant referred to above as being installed at B pits. The plant for which the table is set out is assumed to consist of turbine sets of 500 kw. capacity, of which two are put down at the outset. Ejector condensing plant is allowed for, and Lancashire boilers with economisers and small superheaters. Provision is made in the power house for ultimately installing two further sets, and these are assumed to be put down in the sixth and ninth years. Two boilers are installed at first and three others later, about the end of the sixth and ninth years. The cooling plant allowed for is a large reservoir to serve for the first two years, with subsequent provision of spray nozzles when necessitated by the greater amount of cooling required for the larger quantity of steam condensed. The main switchboard, with all distributing as well as generating panels, is included, and also all necessary accessories, pipework, &c. A 27½ vacuum with water at 75 deg. is allowed for, and also a small degree of superheat, say 50 F. The steam pressure is taken at 150 lb. and a load factor of 50 per cent. is assumed. Coal is taken at alternative prices of 5s. and 3s. per ton placed in the fire hole, and costs are given for both prices. The figures assumed for coal per kilowatt-hour follow closely those obtained in practice with the inferior classes usually burnt at collieries.

It will be seen that the interest and depreciation costs per unit are very heavy in the first few years, giving a high total figure, and the coal cost is relatively small. In the 11th year there is a very large fall in the depreciation cost, owing to the wiping out of the first instalment of capital expenditure. The average cost per unit, taken over the first 10 years, amounts to 0·418d. for coal at 5s., and to 0·366d. for coal at 3s.

The effect of the first few years in raising the general average cost is seen when the latter is compared with the cost in the second half of the 10 years.

Taking the subsequent 10 years on the assumption that the life of the colliery is 20 years, and that, as is probable, the power used will remain practically stationary, from, say, the 10th to the 15th year, and then fall away at the same rate as it has risen, it is obvious that the average cost per unit will be very con-

Total kilowatt-hours for 10 years = 27,500,000.

Maximum annual output = 5,000,000.

Average cost for 10 years with coal at 5s. = 0·418d.

Average cost for 10 years with coal at 3s. = 0·366d.

siderably lower than in the first 10 years, seeing that additions to capital may be taken to have ceased and that the amount of depreciation will become less every few years, while the interest charge is decreasing all the time.

It will also be noticed that the coal cost as well as the maintenance cost per unit tend to become stationary, which points to the fact, apparently recognised with regard to power stations in general, that after a certain output is reached the works cost per unit cannot be further reduced. The minimum reached will be lower, and reached later, the larger the size of generating unit adopted.

It should be pointed out with regard to the costs set out in the table that these are per unit generated, and must be increased to allow for the power taken by the auxiliaries. If we assume the total power taken by all the auxiliaries to amount to 6 per cent. of the capacity of the generating sets running at any time, and the average load on a set to be 60 per cent. of full load, then the power taken by the auxiliaries will amount to 10 per cent. of the total units generated, and the costs obtained must be increased by 10 per cent.

In comparing these figures with those at which power can be obtained from a company the latter should be increased by interest and depreciation charges on the main switchboard and on the building which must be provided for it, as well as the wages charge for any attendance and inspection that may be required for the board. If a proper system of log sheets is kept hourly, as is usually the case in a power house, an attendant will be required for this work, and his wages, or the proper proportion of them, ought to be charged to the cost of power.

The very much lower costs to be obtained after the first 10 years have elapsed, owing to the large depreciation charge on the original outlay coming to an end, and the probability of a considerably larger total consumption of power in the second decade, for reasons referred to previously, should be given due weight in considering alternative schemes, as both these factors tend to produce largely enhanced saving compared with the first decade.

Reliability and General Working.

Important as the economical working of a colliery plant undoubtedly is, equal consideration should also be given to the question of reliability. By reliability is meant not only freedom from breakdown but also freedom from temporary stoppages, causing even momentary discontinuity of the supply.

If the value of the coal lost by stoppages of the haulage plant, &c., due to discontinuity of supply, be charged to the generating costs, it will not require many hours' stoppage in the course of a year to appreciably increase the latter. The loss cannot, of course, be taken as the selling value of the coal, but the difference is probably fairly accurately represented by that value after deducting the price paid to the collier and such items as commission, &c., which are a fixed rate per ton. If this nett value is taken at 5s. per ton, the loss by an hour's stoppage at a pit winding, say, 100 tons an hour would amount to £25, and if several other pits on the colliery are also affected in the same way the total monentary loss incurred will soon assume considerable proportions.

Apart from this commercial aspect of discontinuity, there is the still more important question of safety. In the case of electrically-driven fans the stoppage of the ventilation for any considerable period becomes a serious matter, particularly if it occurs during working hours, when all the men are down the mine. Even if the question of safety does not come in to any great extent, there is at any rate the detrimental effect on the general discipline and efficiency of the mine produced by frequent stoppages.

The question of reliability should therefore be given every consideration in laying out the generating plant, particularly if the installation is a large one. The features which make for reliable working, and to which special attention should be given are :—

Care and foresight in the general lay-out of the plant.
Sound quality and design of the machinery to be installed.
Good methods of working.

Digitized by Google

Competent supervision and strict observance of proper discipline.

Personnel of the staff.

The question of the general lay-out has already been dealt with at some length, as has also that of quality and design of the machinery, so that little more need be said with regard to these points. Price and first cost are so often regarded as the determining factors, not only because it appears economical to spend as little money as possible, but probably also because, in deciding between various alternative schemes and proposals, it is a much simpler matter to consider the few figures represented by their relative costs than to go carefully into the multitude and variety of details necessary for a consideration of their respective merits from the technical and engineering point of view, this usually entailing a very considerable amount of work, and often requiring experience and knowledge of the machinery under consideration only to be obtained by calling in expert advice.

To obtain economy and reliability it is necessary that the plant should be run in a methodical and businesslike way, and it is only possible to get the very best results from it by strict and constant attention to even the smallest details.

The keeping of generating costs is of course essential, and in keeping them great care should be exercised to ensure that everything chargeable is included, so that they may be of real value as a guide to what electric power is actually costing the colliery, and not merely approximate figures for show purposes, erring, and often erring considerably, on the low side. Unless the costs are very accurately kept it is impossible to gauge by means of them the effect of small alterations or improvements on the economy of the plant.

It is, perhaps, more important than anything else for reliable running that defects in the machinery and plant should be attended to and remedied at once, or as soon as it is possible to get at them, and the necessity of being able to do so should be kept in view in considering the lay-out and design of the plant.

The generating sets should be run in regular sequence or rotation, and the period of running of each should be short. If it can be conveniently arranged, it is a good plan to change at least one machine a day. This makes cleaning at frequent intervals possible, and it also ensures that attention to details is not shelved, and possibly forgotten, by letting the faulty machine stand for an indefinite period.

The keeping of a log of the readings of all instruments and gauges in the power house, by the driver, is also an essential feature of good management. Its advantage as a record is obvious, and it also keeps the driver continually in touch with every part of his plant, so ensuring his attention being drawn to any irregularity or fault developing in the running. For a large switchboard and several sets, once an hour is usually sufficiently often for readings to be taken. If they are taken too frequently, the man has hardly got round all the readings before he must start again, so that his energy and attention become devoted mainly to reading instruments instead of to looking after the general running of his plant.

The complete overhauling of each set with its accessories should be carried out at definite intervals of, say, 12 or 18 months. After several overhauls, experience will indicate whether this period may safely be increased, or whether it is advisable to shorten it.

In the boiler house, boilers, economisers and flues should be cleaned at regular intervals, the frequency of which will depend largely upon the quality of the feed-water and the amount of ash content of the coal. Boilers worked at higher pressures require more frequent cleaning than those worked at lower pressures.

A daily record of the quality and quantity of the coal put into the bunkers should be kept. Trouble from steam getting down is nearly always due to the quality of the coal that is being burnt at the time, and the keeping of an accurate and detailed record of coal supplied, besides being necessary for the keeping of costs, also supplies the information required for arriving at what it is possible to burn in the way of fuel without running any great risk of getting the steam down. It further enables the blame to be fixed in the right quarter when there has been trouble from this source.

Proper instructions and standing orders should be in existence with regard to the supply of coal to the bunkers for the week-end as well as for non-working days and holidays, so that there is no danger of the bunkers running empty before the men responsible for filling them are back at work again.

Rules and regulations, though they may be comprehensive and well thought out, are, however, not sufficient in themselves to maintain a high standard of efficiency unless they are supplemented by careful supervision and constant watchfulness on the part of the engineer-in-charge. General slackness, untidiness and wastefulness are sure to result if proper discipline is not strictly maintained.

The question of "personnel" is one which depends to a certain extent on local conditions. The difficulty of getting hold of the right class of man in the boiler house is due to the low wage usually paid, which only attracts an inferior class of man, and to the long working hours, which result in poor firing and general inefficiency, often accompanied by intemperance and frequent "days off." A good fireman is worth his wage, and although his work does not require the same mechanical knowledge as the driver in the power house, he must be able to understand the arrangement of feed and steam pipes and valves, often by no means a simple matter. In addition to this, he has it in his power by his skill and care, or his want of them, to affect greatly the economy of the plant—far more so than the power house driver, who can only do so to a very slight degree. Generally speaking, it is better, where possible, to employ local men; that is to say, men born in the locality or who have lived in it long enough to be regarded as natives, as they are naturally more likely to settle down to their work than the man from another part of the country. The latter usually also labours under the disadvantage of being looked upon more or less as a sort of foreigner, with whom the local men are not always inclined to work quite harmoniously. This may result in misunderstandings between men taking succeeding shifts, by information of occurrences in one shift not being handed on to the man in charge of the next shift.

In the power house the difficulty is to get the right class of man, who will settle down to what becomes more or less a monotonous job, usually noisy, and in the summer time very often exhausting. Probably the best class of man for steam-driven plant is one who has had previous experience of engine driving, and, if possible, also of boiler firing. If he has also a knowledge of how to manipulate switches it is always an advantage, but otherwise he must have sufficient intelligence and interest in his work to learn how to operate the switchboard. He should be so accustomed to running machinery that in the event of anything abnormal occurring he will know how to act properly without losing his head. Too young men do not usually make good drivers; they are often in too great a hurry to act instantly when something has gone wrong without considering whether they are doing the best thing under the circumstances. They rarely seem to appreciate the fact that it is generally better to do nothing at all than do the wrong thing.

It is much the best plan to put the driver on shift in charge of both steam and electrical plant in the power house, and make him entirely responsible. Any other man required for running the plant should be his assistant, working under him.

For a turbine plant, and also for a small engine plant provided the work of opening and closing the valves is not too heavy, one driver can manage by himself so long as only one set is required to be run. If the plant is in good order there is usually no difficulty in his running up, paralleling and changing over to a second set, and the changing over can often be arranged to be done at the change of shift when the two drivers are together. When two sets have to be run in parallel there ought to be an assistant with the driver all the time the two sets are running.

Eight-hour shifts are, of course, the only really satisfactory arrangements for continuous running. In the early days when the load is light and it may be possible to shut the plant

Digitized by Google

down regularly at the week-ends, it is sometimes feasible to work with two drivers instead of three: but even with the break at the week-ends it almost inevitably entails longer hours per week than the men ought to be expected to work. Of course, it is quite customary for winding engine men to work 12 hours every day in the week where there is only one working shift at the pit; but although during winding hours the work is trying and carries with it, part of the time, responsibility for the safety of human life, active winding only lasts about nine hours, and there is usually little work during the night time and at the week-ends.

An arrangement which may be feasible in the early days of the plant, and which is less objectionable than working with two drivers, is to have three drivers, two of whom take day and night shifts in the power house, and the third works as a handy man with the wiremen and fitters. In this way the men get a change from the power house every third week, and may learn something of electrical and mechanical work and repairs, as well as keep in touch with the arrangement of the plant to which the power house supplies power. This outside experience improves the handiness and general efficiency of the men as drivers, and the arrangement has the advantage over only two drivers that the power house can still be run with two men in case the third is off work. The time of the driver who is working outside should, of course, be charged to the job he is working on, and not to the cost of generating.

Centralisation of Power in Collieries.

BY W. E. CHAPPELL.

(Of the Staveley Coal & Iron Co., Ltd.)

Summary.—The author shows that the generation of power for supply to collieries is now being concentrated in large stations which can supply a group of pits in contradistinction to each pit having its own plant. The difference in the problems that have to be faced when direct or alternating currents, or a combination of both, are used are discussed, while in this connection the various classes of load met with in colliery working are described. To obtain satisfactory results the various requirements must be accurately judged and balanced one against the other.

The use of electricity in connection with coal mining has seen, within recent years, a remarkable expansion, and the consideration of the relative merits of the various methods of coping with the problems presented by this class of work is of considerable interest in the light of past experience and present conditions.

Colliery owners who adopt electricity as a motive power are, at the outset, confronted with the difficulty of deciding whether it is best to generate the power required for each colliery in a generating station on the site, or to generate at some central point and distribute by means of high-tension transmission to each pit, and thus obviate the necessity of having more or less responsible charge hands at the various stations by centralising the control under one head. A right decision on this point is of the greatest importance in every way to companies who have a large number of pits within a more or less circumscribed area, and the following considerations are put forward with a view to the comparison of the two methods outlined above, on theoretical as well as on the practical grounds of experience.

The object to be aimed at in the development and installation of a power scheme for colliery work is to secure the largest output with a minimum of capital expenditure and the lowest possible operating and maintenance costs of the plant per ton of coal raised.

In order to arrive at an adequate estimation of the value of one method of power generation and distribution against another it is essential that some detailed consideration should be given, not only to the total requirements of each particular pit so far as power is concerned, but also the varied character of the component parts of the total load entailed by the diversity of operations at the pit, the disposition of these loads during a working day, and the possibility, over a system of pits in the case of a centralised scheme, also of balancing the varied operations in order to secure a steady and continuous load for the generators.

In actual practice it is common to find in the electric equipments of pits, even in very circumscribed areas, that each has been provided with its own generating plant, with capacities ranging from 250 kw. to 1,000 kw., and frequently the plants are duplicated. Speaking generally, however, it may be said that the plants are usually of ample capacity plus a margin of 25 per cent.

There is here, however, indicated a certain amount of provision with regard to possible future requirements when the inevitably extended application of electrical energy has proved itself an advantage to the owners from an engineering and financial standpoint. In actual practice, however, the extension is generally so rapid that such plants are soon running under a 10 per cent. overload, or often more for 15 to 18 hours per day, a state of affairs which is reached before the company may consider itself justified in providing spare generating units. Under circumstances of this description the plant will be allowed to struggle through; and so long as it is fairly able to maintain the output there is quite a strong inducement to owners to temporise and argue about the inutility of spending money on new plant when the old will just about manage to cope with the work.

From the engineering point of view, however, this is a scarcely desirable state of affairs, and brings us to the consideration of the points in favour of a consolidation of power, bearing in mind the desiderata indicated above. For this purpose it will be well to consider: (*a*) Collieries employing direct current; (*b*) collieries employing alternating current; and (*c*) collieries employing a combination of both. The principal factor to be borne in mind is the choice of the site for the station, a choice which is not necessarily so dependent upon geographical considerations as upon the financial. The pit which winds the greatest tonnage is, however, therefore, in the writer's opinion, the most favourable location for such a station for two important reasons: The largest amount of exhaust steam available for the turbine, and the amount of slack available for use under the boilers, though it must be often borne in mind that a third factor to be taken into consideration is the amount of water available for condensing purposes. This last, however, while it may in some cases modify, does not seriously affect the general accuracy of the proposition.

Taking case (*a*), that of a company owning a number of pits within a limited area, each provided with an independent direct-current equipment:—

The concentration of direct-current plants of this character, at their respective voltages, generally 500, would apparently be prohibitive on account of the excessive cost of the transmission lines, though the writer has in mind at least one instance of such a concentration, carried out during the last six months, which is effecting a substantial saving, and this in spite of the initial cost of the line, of 400 kw. capacity, having been £2,500 per mile.

The cheaper and more satisfactory method of connecting pits with direct-current plants is by converting to alternating current, transmitting at 6,000 to 11,000 volts, converting again to continuous current at the receiving end by means of rotary converters. Such a system, moreover, would give the option of taking alternating current down the mine for haulage and other purposes, while confining the application of continuous current to the surface plant. The overall efficiency of such a transmission scheme, using 500 kw. rotaries and transmitting at 6,600 volts, is 78 or 79 per cent. A comparison of the cost of the transmission of 400 kw. a distance of 2 miles yields the following figures :—

Direct Current only.—2 miles at £2,500	£5,000
Combined.—Two 400 kw. six-phase, 50 frequency converters, complete with transformers, switchgear and connections	£2,800
2 miles of transmission line at £365 per mile	£730

A cost per mile of £2,500 for direct-current transmission only, as against £1,765 for the combined scheme.

From the above costs it will be quite obvious that, for the transmission of any considerable amount of power for so short a distance as 2 miles, the alternating-current method has the advantage both in point of cost and the ease with which the voltage may be stepped either up or down and adjustments made to secure the supply of a maintained voltage at any point of application of power. With the increase of the amount of power transmitted the results will, of course, be correspondingly improved.

On the other hand, it is quite feasible to use high-voltage direct-current transmission, and at the present time there is one experimental line actually in operation in this country; but, unfortunately, no data in connection with this have yet been made public, though it is certain that all engineers would be extremely interested if the publication of the results obtained in the operation of the scheme in question were possible.

Turning now to case (*b*) :—There are a considerable number of collieries in this country which are equipped with generating plants coming under this heading, some proving highly successful, others indifferently so, whilst a small minority have proved absolute failures. The failures are attributable to various causes, the most usual of which is the practice followed by engineers of putting down their alternating-current motors of a size more than amply large enough for the service they are called upon to give. This is done under what is proved to be an erroneous impression that such a precaution is necessary for the good of the plant taken as a whole. In other words, the kilovolt-ampere rating of the generator has been reached when the power factor is actually 0·5 to 0·6. A little closer theoretical study, or even a "cut and try" method, would, however, have demonstrated that superior results could have been obtained. These conditions of affairs, however, seem to have been brought about by the endeavour on the part of colliery proprietors to limit the number of different sized motors employed. If, for instance, a load required 22 H.P., they would put in a 30 H.P. machine to do the work, whereas a 20 H.P. would have been ample, as very few manufacturers of machinery have their margin cut as fine as 10 per cent. The following table, which has been compiled from actual tests, will serve to demonstrate these facts, and, furthermore, the last column gives the remedy for overcoming the practical difficulties.

B.H.P. of motor.	Type.	Full load current.	Load on motor. amps.	Alteration.
30	SC	39·0	20	Replaced by 15 H.P. slip-ring.
75	SC	97·5	50	,, 40 H.P. squirrel cage
50	SC	65·0	20	,, 15 H.P. ,,
20	SC	26·0	14	,, 10 H.P. star delta
75	SC	97·5	30	Replaced by concentrating drive on another unloaded 75 H.P. motor and driving through a friction clutch
30	Star delta	39·0	20	Replaced by 15 H.P. squirrel cage motor
10	SC	13·0	6	Replaced by 5 H.P. squirrel cage motor
50	SR	65·0	30	Replaced by 20 H.P. star delta

In a recent case under the author's notice the power factor of the load was 0·62 under these circumstances; but by the substitution of motors of more suitable capacity and the concentration of two or more haulages on a single motor, the power factor was raised to 0·78. It may be further observed that the power factor of this particular plant would be improved by the installation of a rotary converter for lighting purposes, or a self-starting synchronous motor which should be connected to a drive which does not require the motor being started up against a heavy load, such as a centrifugal pump.

Adopting either of the above alternatives, with over-excited fields, the power factor of the system would be raised.

In order to illustrate what has actually been attainable by concentrating electrical power in a system of pits, take two pits situated 1½ miles apart, each provided with its own alternating-current generating plant.

The plant at one pit consists of two sets of 375 kw. and 150 kw. capacity respectively, the other pit having two sets of 225 kw. capacity each. In the first instance the 375 kw. set is only loaded to the extent of 80 per cent., and this only when running during the heavy shift, the 150 kw. set being used for the light load and week-end operations. By a re-arrangement of the motors, the kilovolt-ampere load on the 375 kw. set was brought down to 70 per cent. of full load, and plant No. 2 was loaded to the extent of 60 per cent.

An extende dseries of records (Figs. IA and IB) taken on the two stations and the resultant curve (FIG. IC) plotted demonstrates clearly that only very rarely did the peak loads of the two stations coincide, and by taking advantage of the overload capacity of the 375 kw. set to take care of the peaks, it has been possible to concentrate the power on plant No. 1.

To achieve the concentration in question, a high-tension transmission line was erected for 6,600 volts working pressure, and step-up transformers employed of 400/6,000 volt rating, the line being No. 3 S.W.G. hard-drawn copper with insulators suitable for 11,000 volts working pressure, these latter being used in order that, should the capacity of the line need to be increased at a future date, the only alteration required will be that of replacing the transformers.

The result of this concentration has been the complete shut down of plant No. 2 and the elimination, not only of the cost of six attendants, the reduction of generating costs per unit generated at No. 1 owing to a better load factor, but also of the transfer of control to one point instead of two.

Not only from an electrical point of view, but also from the financial, has this concentration been a complete success, the saving effected paying more than cent. per cent. on the investment, while leaving available for development work at other pits the complete plant of No. 2, consisting of generating sets, switchboards, boilers, &c. Fig. Ic shows the load on No. 1 plant after the concentration of power. This brings us to the consideration of the concentration of power for a greater number of pits, and here, again, the advantages gained are correspondingly great, even more important than the case cited above, as the consumption of steam per kilowatt decreases as well as the initial cost per kilowatt of plant installed, while the question of labour, training of staff and the maintenance of plant resolves itself into a very simple proposition. Whilst dwelling on the advantages attached to concentration such as is outlined, it must be borne in mind, as has been already indicated, that such treatment of power at collieries involves the most careful consideration, more especially in the case of each group of pits, since each group presents special difficulties which can only be effectively surmounted by a close study of the local conditions, due regard having been paid to the possible future development of the particular coal field in which they are situated.

The capacity of the plant should be determined by the disposition of the load, and by arranging to perform certain

operations at certain stated hours, it is possible to have an excellent load factor and to limit the peaks. The load of a pit resolves itself into surface work—that is, screening and works

It may be taken for granted that, as a general rule, the surface work is dependent to a great extent on underground operations, the screening and washing plant motors being inopera-

The underground work being of an intermittent character, the majority of fluctuations in power are traceable to the haulage motors. As these motors are continually starting and stopping, this class of drive is decidedly detrimental to motors of the squirrel-cage type owing to the line disturbances caused in starting up. Drives such as these should be provided with explosion-proof slip-ring motors, and with the finest type of oil-immersed switchgear it is possible to purchase.

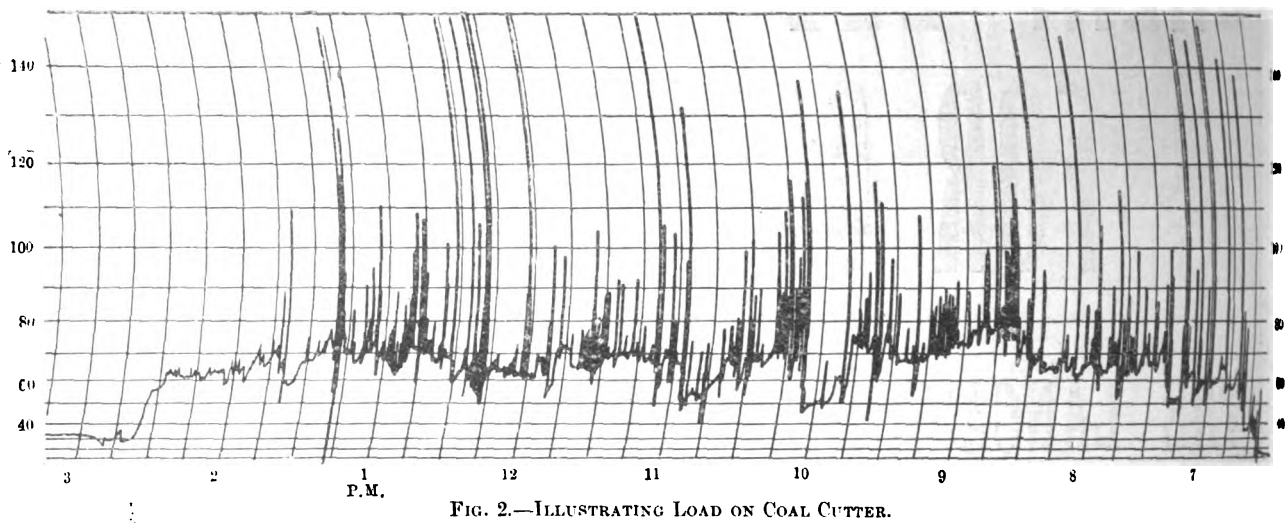

FIG. 2.—ILLUSTRATING LOAD ON COAL CUTTER.

While on the question of haulage motors and their drives, it seems almost unnecessary to add that all such machines should be provided with an efficient clutch, so that where the motor is of the slip-ring type it can be started up against any load, so that it creates the minimum of disturbance on the line, the gradual engagement of the clutch imposing the load upon the motor in a very uniform manner, so that if the load is advanced by any predetermined amount beyond the output of the motor the automatic device will efficiently protect the machine by opening the circuit. Too often haulage motors are not provided with any automatic control gear, while the fuses are worse than useless, as, owing to their constant blowing at periods of overload, the attendant will, to save himself trouble, often insert a piece of copper wire without any regard whatsoever to the blowing capacity of this improvised "fuse." It is practically impossible, except on main haulages, to determine with any accuracy the size of motor with respect to its normal load conditions, as here the personal element enters so largely into the question. At one moment the haulage may be working with perhaps only 20 tubs on the rope, while at the next the number will have been increased to double that figure or, worse still, one of the tubs may be off the rails, being dragged along, thus putting a very heavy load on the motor. There is, of course, not much remedy for contingencies of such a nature, so that in the selection of machines for haulage work it is imperative that they should be large enough not only to do the immediate work of the pit but also to cope with any future developments that can be foreseen. In other words, it may be absolutely unavoidable to put down a 75 H.P. motor for an initial load of 30 H.P., owing to the knowledge that in three or four months' time the load will have increased to 40 H.P. or perhaps more, while if the development of the mine has been rapid it may have come up to nearly full load.

Coal-cutting motors provide both a constant and intermittent load, according to the type of cutter employed, one type probably working for hour after hour without giving any trouble whatever, while others are continually starting and stopping, owing to troubles occasioned by the cutter choking and causes of an allied nature. With a coal cutter operating continuously, however, the load is in reality slightly intermittent, as the appended curve (Fig. 2) demonstrates, the motor in this case being well adapted for its work, as is seen by the fact that the most efficient point on the load curve as regards power factor is three-quarter load, and the motor in actual practice operates during the greater portion of its periods of service at 70 to 90 per cent. of its full load capacity.

In coal cutting it is possible to do all the cutting on the light shift, and by so doing the load on the generating station is equalised.

With heavy pumping underground it is necessary in designing a power scheme over a system of pits—having duly in mind the centralisation of the power generation—to provide as nearly as possible a constant load on the system if the greatest advantages are to be derived. The ideal load on any system is, a short period; and, in fact, in planning a transmission scheme, this point should be kept in mind in order to provide the desired equalised load for 24 hours, as this will admit of a smaller installation, with a consequent reduction in capital expenditure, also a cheaper cost of production in consequence of the constant nature of the load on the plant.

Motors driving screening plant may, as a rule, be arranged to run constantly during the shift, although the load on some

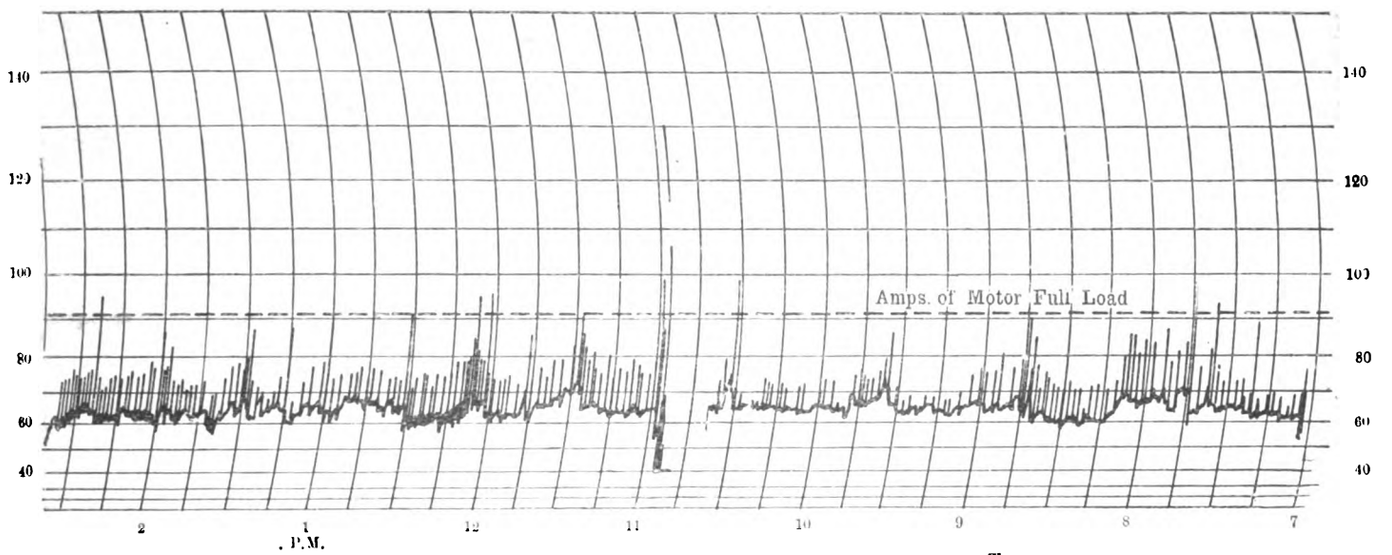

FIG. 4.—FULL-LOAD CURRENT OF MOTORS AND ACTUAL AMPERES TAKEN BY THEM.

of course, a constant load during the 24 hours, though such conditions are rarely obtained except in the case of chemical works and others of a similar nature. It is quite possible, however, in adopting a centralised scheme such as has been outlined, so to arrange the load that it will be nearly constant during the 24 hours of the day. This is especially the case if there is a certain amount of pumping work to be done in the pits.

of the motors, such as those operating the tipplers, and the chutes, will be of an extremely variable character. It is possible, however, by having these fitted with good friction clutches to operate them continuously, which method tends, furthermore, to reduce the shocks on the transmission system. On the other hand, on such motors as those employed for raising and lowering the chutes, the load being of such an intermittent nature it is advisable to instal motors with as small a

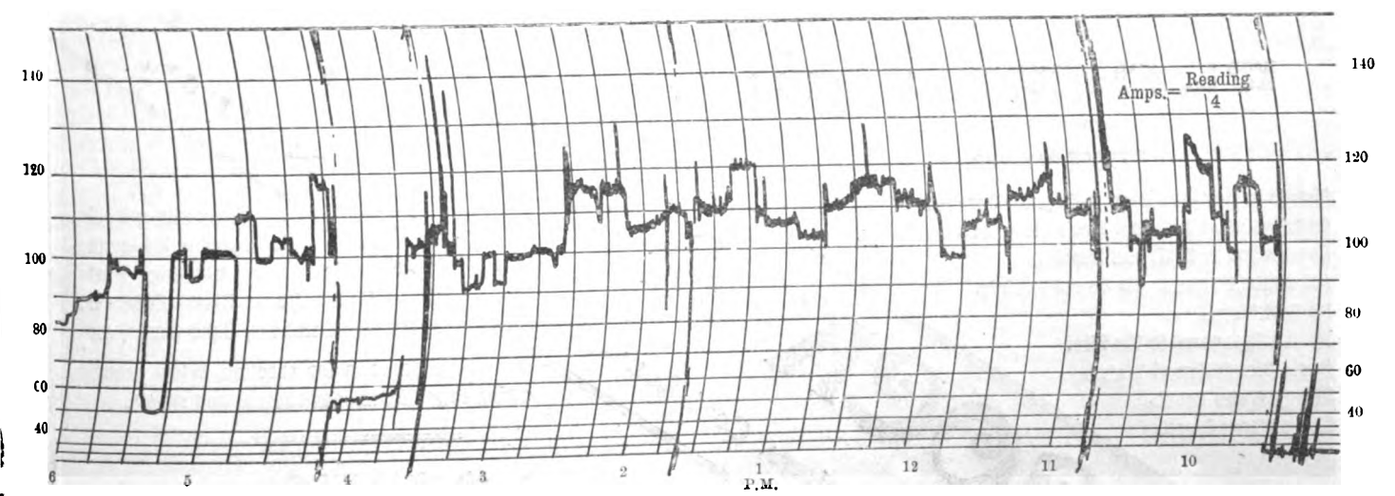

FIG. 5.—ILLUSTRATING LOAD ON ELECTRICALLY-DRIVEN FEED PUMP.

If sufficient standage is afforded for the water, it is possible to carry out the underground pumping at periods of what would ordinarily be light load, thus providing an equalisation of load on the day's work. Taking, for example, a pit accumulating water at the rate of 200 to 300 gallons per minute; by providing an adequate standage it is quite feasible to pump the water at the rate of 800 to 1,000 gallons per minute during

margin as possible and allow the overload capacity to take care of the excess load. This, in the case of alternating-current plants, is very important, as it ensures a fairly good power factor on the motors. The screening belts provide a very constant load on the motors which drive them, and this is one of those instances where, by adopting the common practice of putting down motors more than large enough for the

work the power factor is likely to be considerably reduced, as the Figs. 3 and 4 will demonstrate. The dotted line drawn through the curve represents the full load of the motor, while the irregular line shows the actual load existing in practice. While on the subject of motors operating constantly, the curve (Fig. 5) illustrates the load imposed by an electrically-driven feed pump. In one such instance, by putting in a boiler feed pump well adapted for its work it has been possible to reduce the steam consumption in the colliery plant to such an extent that one boiler has been laid off, and there is, further, no doubt that the superiority of an electrically-driven over a steam-driven pump is very great.

If the ventilating fans are electrically driven, the greatest care must be exercised in choosing the motor, and such a drive is an ideal one for a synchronous self-starting motor, and confers the advantage of having on the transmission line a synchronous piece of apparatus, thus affording every opportunity for improving the power factor of the system. One prominent manufacturer has on the market to-day a self-starting synchronous motor which readily lends itself to such drives as those of centrifugal pumps and ventilating fans. This motor is started up by switching it direct on to the line, and after picking up speed, the exciter (which is usually wound for about 35 to 40 volts) is switched on to the rotating field, and by adjustments of the field strength it is possible to raise the power factor to a very good figure indeed. Ventilating fans are what might be termed "dead" load, as there is practically no fluctuation in the powers taken by them.

It is most important to have the motors driving machine tools operating at constant load, owing to the varied character of the repair operations carried out. Individual driving would tend to improve the load conditions on the plant, but in ordinary pit work it is impossible to capitalise the pit with such an expense as individual motor driving of all tools. Ninety-five per cent. of the fitting and repair shops, it would be safe to say, are driven by a single prime mover, and wherever enquiries upon this point have been made there has always been elicited the same opinion—*i.e.*, that individual motor drives have not been applied simply because of the great initial cost. The smith's fan, however, should be always independently driven.

From the foregoing brief analysis of the characteristic load of a colliery installation it will be seen that, if an intelligent view is taken of present needs and future possibilities, it is possible to connect up a number of pits in a general scheme, and to secure as a result of such a concentration lower costs per unit, because of cheaper steam production, the possibility of using larger generators, the ability to balance the various loads in the day's work, more efficient control and staff, less labour costs in a central station than in the total of individual stations, generation and transmission at high voltage and flexibility as against the waste incurred in capital expenditure on so many different stations, none of them fully loaded in the true sense of the term, but still taxed to their utmost capacity owing to excessive margins in the motors, with an intermittent and ill-adjusted load, supervised by separate staffs with their heavy labour cost.

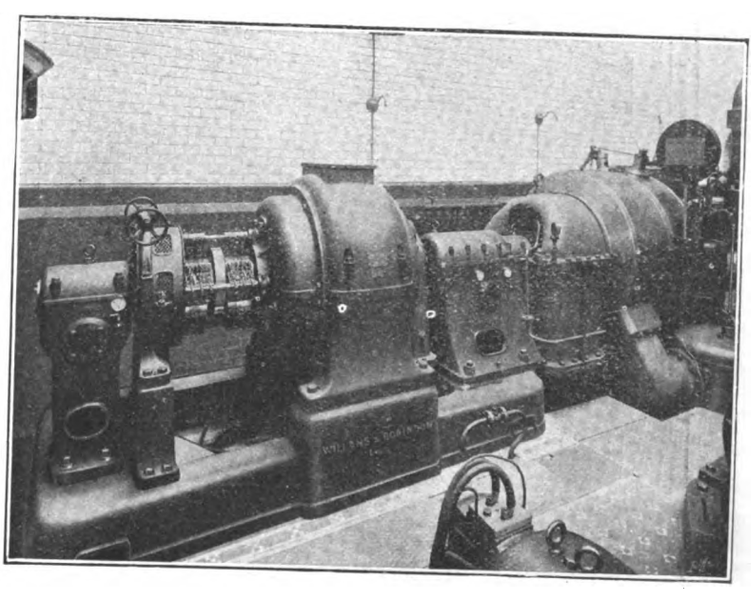
In conclusion, the writer would say that, in his opinion, the whole question of the centralisation of power generation and transmission resolves itself not so much into hard and fast rules as in taking a broad though none the less exhaustive view of the factors presented by any system of pits, accurately judging the requirements of each, the nature of the load at different periods of the day, the balancing of these requirements as far as possible one against the other, the arrangement of various operations so as to provide uniformity in load, the adjustment of the machines to the work they have to perform and the selection of the most efficient motors and control gear. Given such an appreciation of the problem presented, there is no obstacle to the creating of such a centralisation as will give the highest possible efficiency with a minimum of cost.

The advantages of such a method over that of individual plants will be and are at the present time apparent in the great annual saving effected in wages, maintenance and repair, not forgetting capital expenditure, a saving which may mean all the difference between an indifferent and a substantial dividend for the shareholders.

Finally, it may be remarked that the employment of exhaust or mixed-pressure steam turbines in connection with colliery work has given a great impetus to electrical driving, by the adoption of which drive there is no reason to doubt that substantial improvement could be effected in 90 per cent. of the colliery undertakings now operating their own plants. Given the willingness of colliery companies to meet the first outlay with regard to such a scheme and plant as has been outlined, there is no question that a careful investigation of the claims made for this method of dealing with colliery power is fully justified by actual practice and results.

Impulse Disc and Drum Mixed Pressure Turbine.

Among recent improvements in turbine design, one of the most important is the combined impulse and re-action turbine. Messrs. Willans & Robinson, of Rugby, have adopted this design as their standard for all high-pressure and mixed pressure work, and the accompanying illustration shows the plant which has been installed in the power station of the Bridlington Corporation.



300-KW. WILLANS MIXED PRESSURE TURBO-GENERATOR AT BRIDLINGTON.

The electrical generator is of the Siemens standard direct-current type, being fitted with ventilated commutator and having a normal output of 300 kw. at 440 to 500 volts, when running at a speed of 2,700 revs. per min. The full output can be obtained when the turbine is supplied with exhaust steam from the existing engines, or any mixture of exhaust and live steam. The turbine will also give its full load, 25 per cent. overload, and a non-condensing output of 250 kw., on live steam.

Although the plant has not been installed for more than a short period, very satisfactory results from the economical point of view are being obtained with the combined plant, as compared with the engine-driven sets alone. Even when running on high-pressure steam the results are much better than when the engines alone were run condensing.

Messrs. Willans & Robinson have installed a large number of similar machines which are giving equally good results. Among those working at collieries may be mentioned the mixed-pressure sets at the Blairhall Colliery, Fife; the Rothervale Collieries, near Sheffield; and the Tredegar Coal and Iron Co.'s Collieries in South Wales; also the plain exhaust set at the Pleasley Colliery, near Nottingham.

Notes on Switchgear for Use Underground in Mines.

BY H. W. CLOTHIER, A.M.INST.C.E., A.M.I.E.E.

Summary.—After referring to the events of the last two or three years and their bearing on the design of electrical plant for mines, the author deals with "explosion-proof" gear and points out its limitations. The proper provision of cable connections is then emphasised and the combination of plant, such as switch-gear and transformers, is discussed. A pit lighting system is introduced. Continuous-current automatic switches present difficulties, if of the air break type, owing to their bulk when enclosed; on the other hand, if oil is used it carbonises, but this seems the better solution of the two. The problem of automatic protection, a "balance system," meets many cases, and warrants the special consideration of mining engineers, particularly as applied to leakage devices. Finally, a general lay-out is briefly described.

In the last special Mining Issue of THE ELECTRICIAN, an article was contributed by the writer on the subject of "Switchgear for Mines." Since then several historical events have occurred, including the memorable mining tragedies at West Stanley, Whitehaven and Hulton. Neither of these catastrophies have been attributed to the use of electricity, but they have had the effect of bringing home to everyone concerned the necessity for the most stringent precautions in the design of electrical equipment. The three years which have passed have been eventful in other ways. For instance, the appointment of a Chief Electrical Inspector of Mines and a Departmental Committee to enquire into the working of the special rules for the use of electricity in mines, and to consider any amendments required. Moreover, the large Engineering Institutions have devoted several discussions to the use of electricity in mines, and an entirely new and active organization has been formed by mining electrical engineers, one of the first objects of that Association being to consider means for minimising the risks attending the application of electricity to mining, and to promote the adoption of new methods and devices tending to increase safety.

It is natural that such events should reflect themselves upon the design of apparatus, therefore, and it is of interest to consider the present position as compared with that recorded in the 1908 issue. For this purpose it may be permissible to quote the following requirements which were said to apply to switchgear construction.

1. Accidental contact with metal whilst alive must be impossible.
2. The insulation must be able to withstand any excessive pressure that is liable to arise, even under abnormal conditions.
3. The design should not allow dust, dirt, moisture, or vermin to diminish the insulation.
4. Fire risks must be reduced to a minimum.
5. There should be a minimum amount of cleaning necessary to maintain the gear in a good condition.
6. Parts requiring inspection and cleaning must be capable of ready and absolute detachment from the gear to enable such operation to be carried out with safety.
7. The sectional area of conductors must be such as to carry without deterioration the maximum overload to which they are liable.
8. Moving parts, such as switch mechanisms, must be situated where they can be observed, and chance of switches sticking must be reduced to a minimum.
9. Automatic protection to be included which will isolate a faulty section without interference with healthy sections.
10. The construction to be mechanically strong in order to resist rough usage and accidental impact.
11. The switches must be capable of breaking, without disturbance to other parts, the maximum power which may instantaneously pass through the switch when acting under the worst fault conditions.
12. The simplest construction is required consistent with economy in operation and maintenance costs."

In the light of recent experience there is nothing in the above points which does not apply at the present time for ordinary mining purposes, but it is necessary to enlarge upon these in order to arrive at a correct understanding of switchgear and accessories as required underground.

The main risks are due to shock, fire and explosions. The fire and stock risks are common to any electrical equipment, whether below or above ground, and it is of interest to observe that adequate provisions against explosions form at the same time the best safeguard against risk of shock and fire.* Broadly speaking, therefore, the ideal is obtained by an explosion-proof construction.

The term "explosion-proof" as applied to switchgear is of more or less recent introduction, and its meaning might well be questioned. If it is intended to carry with it a guarantee against explosions in mines, it is certainly an ambitious term, although it is perhaps more legitimate than the description "safety lamp." "Flame-proof" is a more modest definition, but it is hardly broad enough. The requirement really is for an apparatus which must be flame-proof when an explosion of the maximum force occurs inside; that is to say, under no circumstances whatever should there be an external flame or spark sufficient to ignite gas. "Open-sparking" is a new

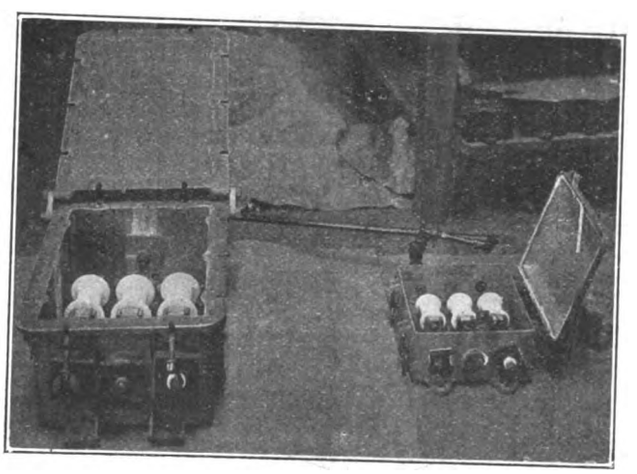

FIG. 1.—AN OLD EXPERIMENT WITH AN "EXPLOSION-PROOF" AND A NON-GASTIGHT JOINT RESPECTIVELY.

definition which occurs in the recently revised rules, and there it is said to mean sparking which, owing to the lack of adequate provisions for preventing the emission of inflammable gas external to the apparatus, would ignite such inflammable gas. In course of time this may introduce the term "open spark proof," or perhaps "sparkless," apparatus. Whatever is the outcome, it is at present obvious that the old definition "gas-proof" will die out as the difficulty of making any apparatus which would be permanently gas-tight in a mine is now fully recognised. The development in this direction is partly due to the experiments which were made at Messrs. Reyrolle's works upon apparatus shown in Fig. 1, by which it was found possible to ignite the most explosive mixture of town gas and air inside the larger box without any visible flame, whereas a similar ignition in the smaller box with the gasket joint a flame protruded outside at every test. In consequence of this experience† strong boxes were made which

* Mr. Robert Nelson, "Electricity in Mines—The Avoidance of Accidents," read before joint meeting of the Colliery Managers' Association and the West of Scotland Branch of Association of Mining Electrical Engineers in Glasgow on April 1, 1911.

Digitized by Google

were calculated to withstand an internal pressure up to 200 lb. per square inch. This was considered sufficient in all ordinary circumstances to justify the term "explosion-proof." An example of an air compressor motor starter designed on these lines is shown in Fig. 2, and a switch-fuse box in Fig. 3. The same form of enclosure as used for automatic oil-breaks witches is shown in Fig. 4. In this instance the switch is mounted upon a pillar for controlling a three-phase motor. Incidentally, it should be noted that the illustration also shows a double three-core terminal box suitable for receiving metallic covered cables.

Obviously it is preferable to reduce the space inside any box to a minimum in which gas could accumulate, more especially as, unless the cubical contents of the box are kept within reasonable dimensions, the thickness of the metal necessary to resist the pressure occasioned by an internal explosion becomes prohibitive. For that reason, it is better to enclose all conductors in oil or in compound, thus precluding as much air as possible. This condition mitigates against the use of fuses, particularly for distribution boxes where there may be a large number of ways. It is, of course, not suggested that explosion-proof apparatus is essential in all mines or even at all places in any mine. On the contrary, in places where there are no risks of explosion due to gas or coal dust, it remains only to provide apparatus which will guard against risks of

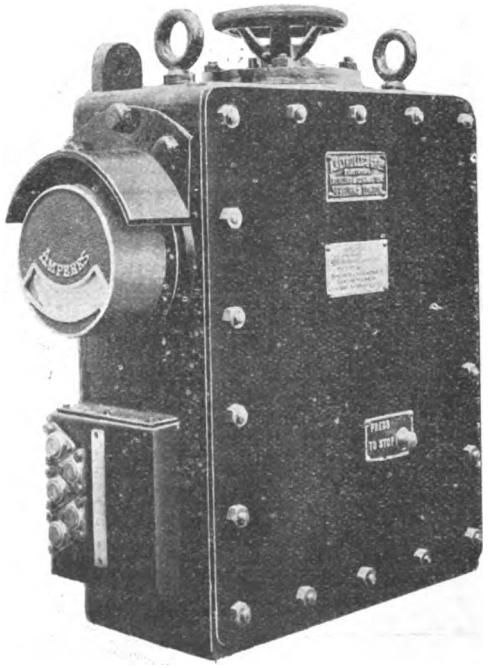

FIG. 2.—CONTINUOUS CURRENT DRUM TYPE MOTOR STARTER, FOR PORTABLE AIR COMPRESSOR. MOUNTED IN "EXPLOSION-PROOF" CASE.

fire and shock, and it would appear that these contingencies are best met by a properly earthed metallic armouring; some saving may therefore be effected in the initial cost of switchgear by installing apparatus which, though not explosion-proof, is properly ironclad or otherwise enclosed. In many mines, however, in view of the difficulty in discriminating whether there are risks of explosion or not, it would be the best practice to use explosion-proof type throughout for underground work.

Cable Connections between Plant.—The time for the universal adoption of the "all-armoured" installation seems now nearer to hand. The conductors of a trailing cable in a mine appear to be the only ones where any real difficulty is met, and even some trailing cables have been made with a copper earth screen wound in a spiral over the dielectric and protected by rope, leather, or other covering. One of the essentials to the "all-armoured" installation is that the switchgear and accessories should be properly designed to accommodate the cables which are to be connected up. This is, in fact, an essential feature in ironclad design, and its importance is sometimes overlooked by the manufacturer and user of the apparatus. For instance, it is sometimes solely in consequence of this oversight that unarmoured cables have to be resorted to for connections between switchgear, transformers and motors respectively on installations which are in other respects all-armoured. In the writer's opinion there should be no need for this. Motors and transformers and switchgear can be easily fitted with proper terminal boxes. Fig. 5 is intended to illustrate the interconnection between switchgear and motor; connections to static transformers can be treated in a similar way, provided the necessary study is given to the terminal design.

the smaller sizes of transformers, is to combine the transformer and switchgear into one mechanical apparatus. In Fig. 6 the switch is mounted on the case enclosing the transformer, the combined apparatus being mounted on wheels, plugs into 'bus-bar or terminal connections.

For pit lighting where very small transformers are used it is possible, by devoting special attention to the winding insulation in order to ensure against breakdown, to dispense with switchgear entirely on the high-tension side of the transformer. A simple arrangement is shown in Fig. 7. In this connection it

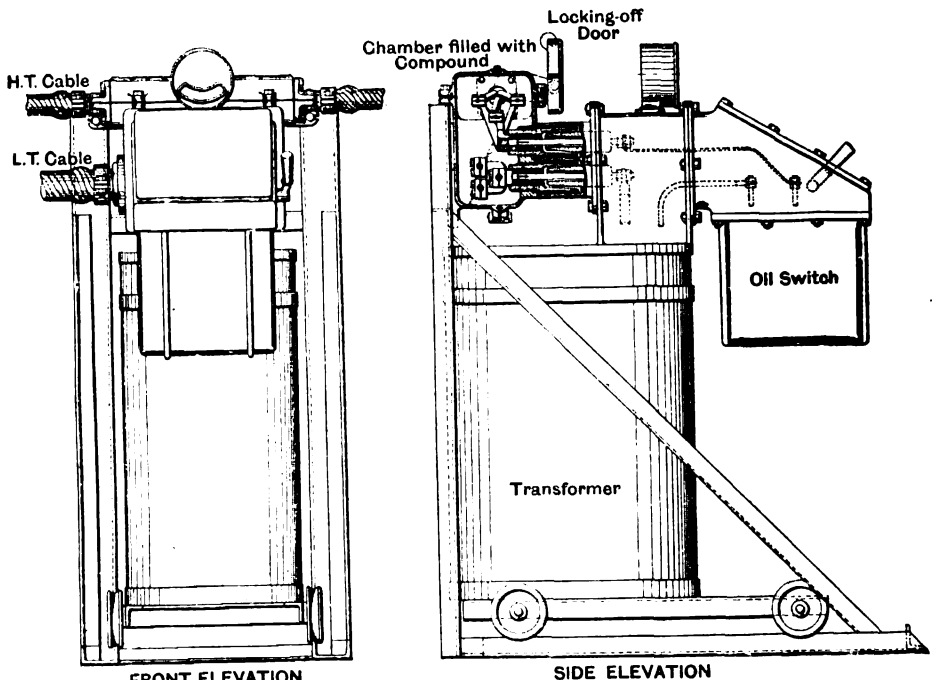

FIG. 6.—COMBINED TRANSFORMER AND OIL SWITCH

FIG. 8.—EXPLOSION PROOF AUTOMATIC SWITCH FOR LIGHTING CIRCUITS.

is well to remember that the use of metallic filament lamps simplifies the problem by reducing to some extent the output of the transformer.

An automatic switch for lighting-circuits is recommended in preference to fuses, and a suitable type of switch for this purpose is shown in Fig. 8. The case of this switch is so constructed that the circuit cannot be operated whilst the lid is open. It

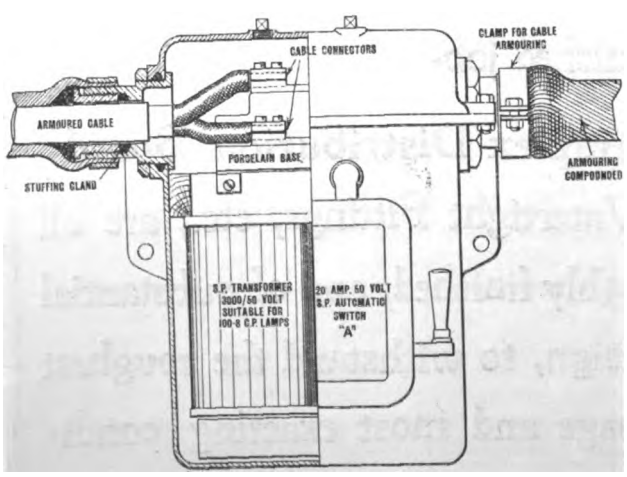

FIG. 7.—COMBINED CABLE JOINT BOX, TRANSFORMER AND SWITCH FOR PIT LIGHTING.

will be noted that the lid is provided with a machined metal flange joint similar, but on a smaller scale, to the explosion-proof apparatus described above.

The Inspection of Switches.—The isolation of parts of switches prior to inspection has received special consideration in the design of switchgear. In some cases isolating switches are provided for the purpose of disconnecting the conductors in a panel from the 'bus-bars, but undoubtedly the most effectual means for ensuring safety in this respect is obtained by the "draw-out" type of switch. Examples of this form are shown in Figs. 9, 10 and 11. These panels may be constructed for use as single panels with cables leading in and out horizontally or vertically to suit the particular situation in which they are placed, or, as shown on Fig. 11, a row of panels may be lined up to form a distribution switchgear, the 'bus-bars being enclosed in a chamber made up in sections and run up solid in insulating compound.

Direct Current Automatic Switches.—The type of automatic circuit breaker for use on direct-current circuits in mines calls for some special consideration. Considered from a circuit

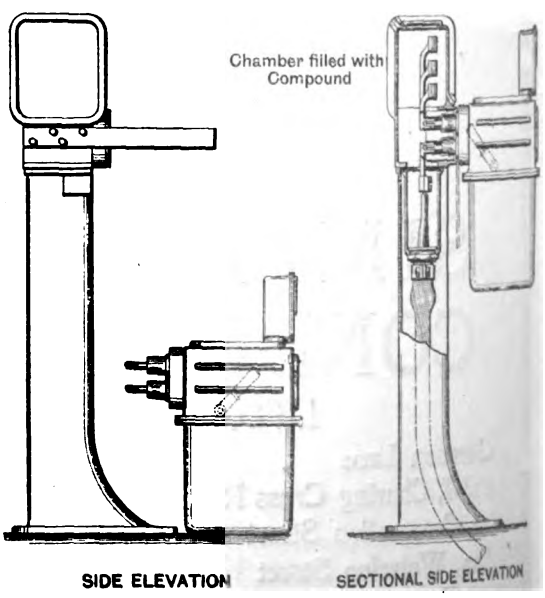

FIG. 9.—SOLID TYPE ARMOURED PILLAR SWITCHGEAR.

rupturing point of view, the approved practice is to use circuit breakers with a long break across carbon blocks in air. For large capacities, however, it is difficult to enclose such breakers in metallic cases owing to the clearance required over the break to avoid arcing to the case. Breakers with magnetic blowouts overcome this objection to some extent, but even this involves enclosure in boxes having a large cubic capacity of air

Digitized by Google

and, as in the case mentioned above, to be explosion-proof this necessitates very heavy castings. In the natural course of events one resorts to an oil break in consequence of its universal use on alternating-current circuits. It has been found that the principal objection is the excessive carbonization of the oil when the switch is called upon to break heavy currents frequently. The reason for the extra precipitation of free carbon as compared with alternating-current circuits is due to the fact that a direct current arc generally hangs on longer and is more intense than an alternating-current arc when rupturing an equivalent circuit. The adoption of the oil-break principle for direct-current switches, therefore, necessitates more frequent inspection and renewal of the oil, and preferably a construction of more liberal dimensions.

It was at one time thought that the use of oil-breaks on direct-current switches was prohibited by the risk of dangerous pressure rises on heavy inductive loads. This argument still prevails in some circumstances, but very rarely in actual conditions of working in mines where the average load is sufficiently non-inductive to ensure against a pressure rise likely to puncture ordinary insulation, and, indeed, oscillograph records have recently been shown* to prove that the pressure

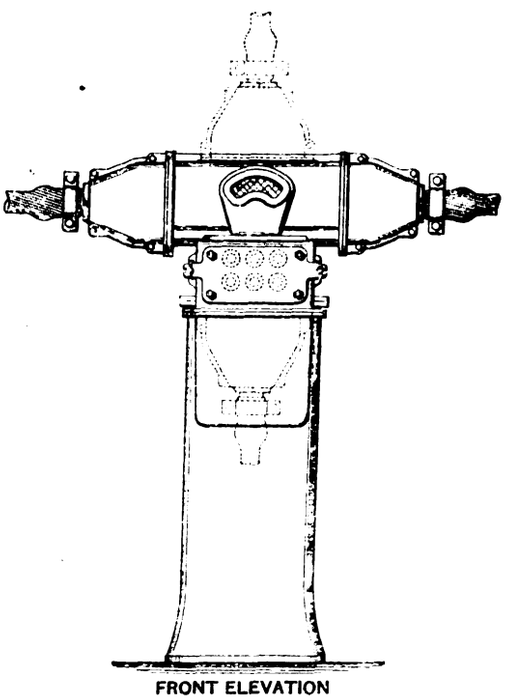

FIG. 10.—ARMOURED PILLAR SWITCHGEAR.
(Dotted lines show alternative positions for cables.)

rise on an oil-break switch is no more than that occasioned on rupturing a circuit by means of a strong magnetic blowout. Subject therefore to effective maintenance, an oil-break switch bids fair to be a useful direct-current accessory, more particularly when it is essential that the switch be of the explosion-proof type.

Automatic Protection.—As a general rule it may be taken that it is more difficult to prevent switches tripping out at times when they should hold in than it is to make a switch trip out at the right time. The "Merz-Price" balance system of protection which has been evolved for the purpose of isolating faulty sections without interfering with sound ones, is hardly applicable for universal use underground on account of the initial cost of the pilot wire and the maintenance of the same. When considering transmission above ground, and the interconnection of sub-stations, it is another matter, as the necessity of maintaining a continuity of supply to consumers under all conditions warrants the expense, but ring mains and duplicate feeders are not always possible in mines; and, although it may be inconvenient to shut down one section of the mine for a fault on another, it is not generally so serious a matter as the isolation of one consumer on a power company's network on account of a fault on a cable connecting another consumer. At the same time the more nearly a mining equipment approaches the ideal transmission equipment in regard to automatic protection the better, provided, of course, no complicated apparatus costly to maintain is thereby introduced. For this reason it has been suggested that the setting of relays and the methods of protection adopted at different parts of the connections under-

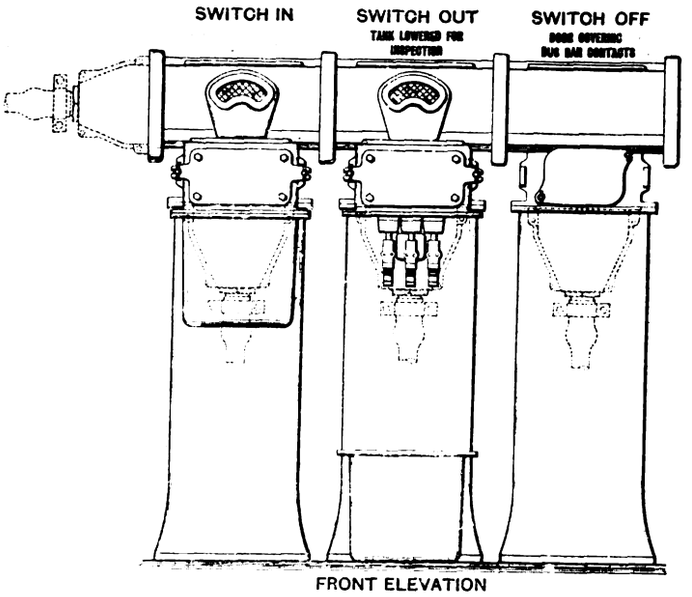

FIG. 11.—REYROLLE IRONCLAD MINING PANELS.

ground might well receive more attention. It is now a regulation that a proper plan should be kept in the office at each mine showing the position and sizes of all fixed apparatus in mines, and the plan must be kept reasonably up-to-date. It is very little extra trouble to add to this plan particulars of the automatic protection, the blowing capacity of fuses, the setting of overload or leakage protection tripping devices, &c.

Leakage Protection.—It will be observed that the introduction of leakage protection devices into discussions on mining

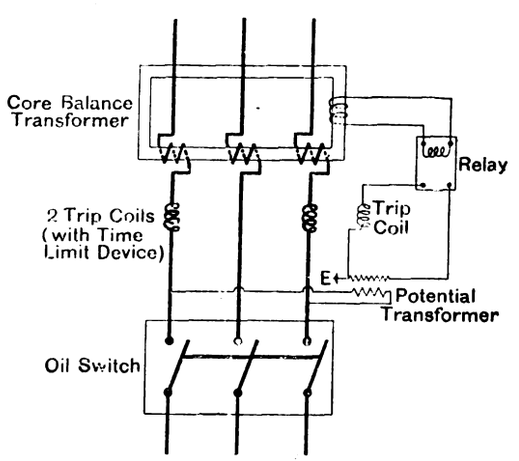

FIG. 12.—LEAKAGE OR CORE BALANCE PROTECTION WITH RELAY FOR LIGHT SETTING.

apparatus has occurred during the past two or three years, and it is questionable whether much headway has been made in practice. There is no doubt, however, that more attention will be given in the future to this subject on account of the recommendations contained in the report of the Electricity in Mines Committee. One of the main objects of leakage protection is to isolate instantaneously a circuit upon which a fault to earth has occurred, more particularly with a view to

* Mr. Alfred G. Collis, "Breaking High and Low Potential Circuits," read before the South Wales Institute of Engineers in Cardiff on February 23, 1911. THE ELECTRICIAN, Vol. LXVI., p. 869, 894.

Digitized by Google

avoiding the risk of "open-sparking" at the fault. Hitherto the switches with so-called instantaneous overload release have had the objectionable feature of tripping out on temporary overloads, whereas leakage protection can be provided to trip out at an earth fault amounting to a small percentage of the normal load, say 5 per cent., whilst it holds in for any transitory overload. At the same time it has the advantage that it may be incorporated with a time limit release for protection against persistent overloads and faults between phases. An example of the connections is shown on Fig. 12. A relay is used here for the light setting, but in an alternative method the current in the protective system, induced by a fault to earth, operates directly upon the tripping

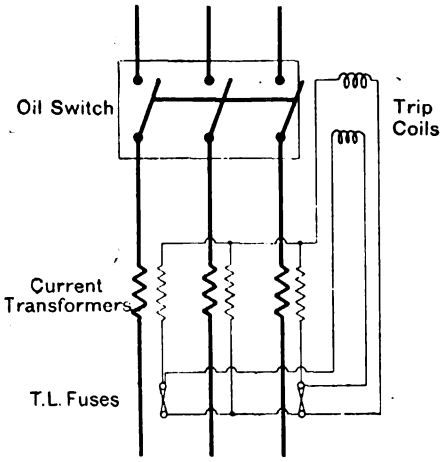

FIG. 13.—INSTANTANEOUS LEAKAGE AND TIME LIMIT OVERLOAD PROTECTION (WITH DIRECT TRIP).

mechanism of the switch. In this case the connections are somewhat simplified as shown in Fig. 13, but owing to the amount of power required to trip the switch, the setting is less sensitive. Under ordinary circumstances there is no difficulty in setting the gear to trip at a fault current of about the same amplitude as the normal working current per phase.

Many automatic overload switches are now constructed with series trip coils for voltages up to 3,000. In some of these cases the use of leakage protection involves the addition of

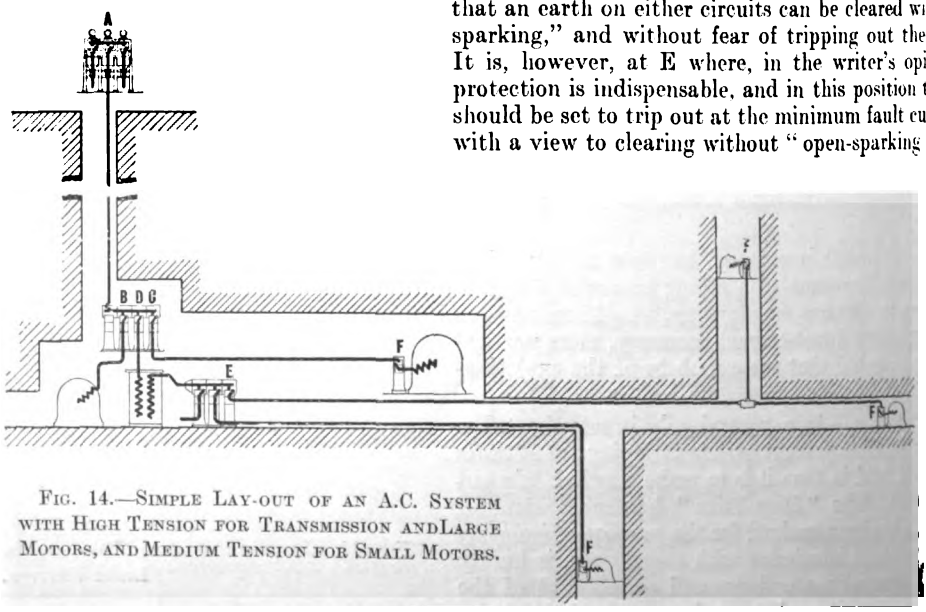

FIG. 14.—SIMPLE LAY-OUT OF AN A.C. SYSTEM WITH HIGH TENSION FOR TRANSMISSION AND LARGE MOTORS, AND MEDIUM TENSION FOR SMALL MOTORS.

current transformers. With this exception, however, the system is no more complicated than ordinary overload protection. In order to study the application of leakage protection it is necessary to consider the general lay-out of the system. The diagram in Fig. 14 is taken as a typical case. It is supposed that there is only one shaft cable, and that a 3,000-volt supply is taken directly to large motors near the shaft bottom, and a medium pressure supply is distributed to smaller motors in bye. It is assumed that all conductors are armoured, and that the armouring is connected to a proper earthing system at bank, the neutral point on both the high and medium pressure being earthed. The several points at which protective devices could be installed are at A, B, C, D, E and F. The switch at A controls the whole supply to the pit, and the protection, to be ideal, should not trip unless there is a serious fault on the bus-bar at the pit bottom or on the shaft cable. In all probability the circumstances are such that there is very little risk attending such faults and, moreover, the situation is such that no serious

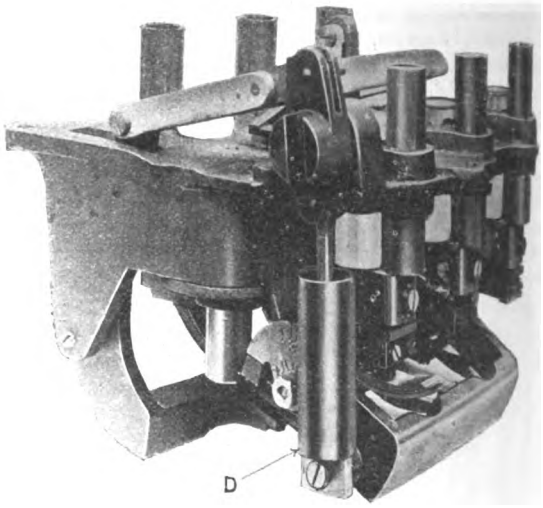

FIG. 15.—WORKING PARTS OF SWITCH, SELF-CONTAINED AND DETACHABLE FROM THE CASE.

D = Dash-pot for automatically grading the setting of the overload release between starting and running positions.

harm would result from the remote chance of the fault hanging on for a second more or less. The protection at A might, therefore, well be set for overload time limit to trip with a persistent overload of two to three times the full load current. The switches at B, D and C should have their overload setting at least one-third that of the switch at A, in order that each circuit may have the chance of opening for a fault on itself without interference with the others. At these places leakage protection at full load setting might be used to advantage so that an earth on either circuits can be cleared without "open-sparking," and without fear of tripping out the switch at A. It is, however, at E where, in the writer's opinion, leakage protection is indispensable, and in this position the protection should be set to trip out at the minimum fault current to earth with a view to clearing without "open-sparking" a fault such as would be occasioned by a fall of roof on the cable. At F (*i.e.*, the motor panels), ordinary overload protection is sufficient, the setting being lighter than the overload setting at E in order to reduce the chance of E tripping out for a simple overload on the motor. (According to one method adopted in switches for small squirrel-cage motors, the overload setting at F can, by a simple device, be made self-adjustable from a heavy setting at the starting position to a light setting

Digitized by Google

running. The method of accomplishing this is shown in Fig. 15. The lever controlling the position of the core of the tripping magnets is raised by the dash-pot in the operation of closing the switch, and the dash-pot allows the core to drop gradually whilst the motor is running up to speed.) As an alternative to the above sequence of protection the switch A might be the only one fitted with leakage protection. This may be simpler but, on the other hand, it has the objection that the whole electrical equipment in the pit would be shut down for a small leakage in any section.

Duplicate Feeders and Ring Mains.—Let us now consider a case of a mine using more electrical power, including a number of large motors for underground haulages, pumps, &c. A lay-out of this kind is represented in Fig. 16. A complete stoppage would be a more serious matter and, in order to deal with the power required, it is assumed that it would be a good commercial proposition to have duplicate shaft cables. Then it is essential to consider some different system of protection from either overload or leakage protection, and the only satisfactory solution so far is to use the well-known balance system with pilot wires. The pilot wires in this case are not so formidable an objection because the pilots for both of the main shaft cables can be combined in one armoured cable. The switches therefore at A and B need not have any overload protection, but they should have some

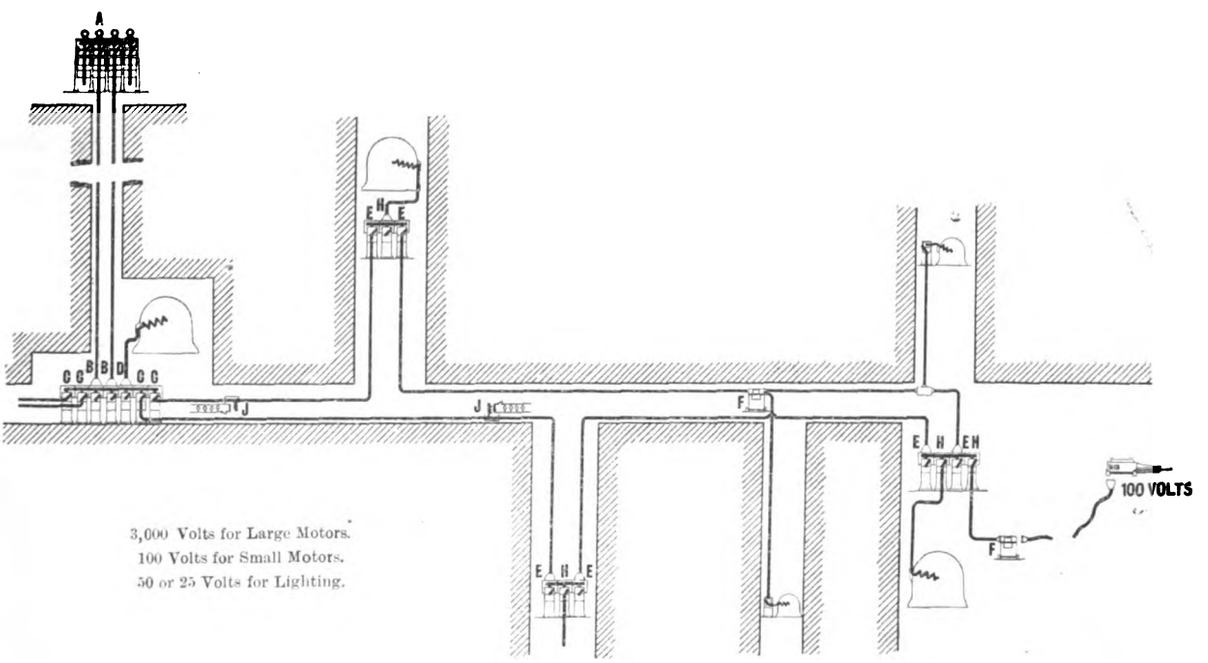

FIG. 16.—HYPOTHETICAL LAY-OUT OF A.C. SYSTEM WITH LARGE AND SMALL MOTORS, ELECTRIC COAL CUTTERS AND ELECTRIC LIGHTING.

balanced system which would trip out the switches instantaneously at each end of the individual cable developing any kind of fault, in such a way that no other switch should be affected at the same time. Between the switches at A and the generators there should be some overload device with a long time limit in order to guard against the continuance of a 'bus-bar fault on other distribution switchgear at the pit bottom, as the balance gear would not trip out on that occurring. A fault of that kind should be very remote occurrence indeed, and particularly on properly constructed switchgear having all its conductors run in solid in compound or oil.

The switches, C, on the distributors at the shaft bottom form part of separate ring main systems. The ideal protection would be the balance system, and if the ring main were above ground with a similar load the balance system would probably be adopted; but underground, as discussed before, the question as to the advisability of the pilot along the roads enters into the consideration. Unfortunately a proper balance system without the use of a pilot has yet to be developed but in its absence the ring main can be run with one of the switches E, open; in the event of any section of the cable being put out of commission by a fault, the supply could be quickly re-established throughout by manipulating one or more of these switches in order to open the ring at another place. The same points, therefore, as regards the use of leakage protection apply here as for the lay-out with single cables, so that at C a leakage protection of light setting, say 10 per cent. of normal full load, incorporated with a time limit overload to guard against faults between phases would probably give the best results. Automatic protection on the switches at E might well be dispensed with, and a lighter leakage and overload protection would fulfil the requirements of switches in such places as those marked H on the diagram. The same remark would apply to the switches at F. Incidentally it should be stated that the places at which these are fixed are those where the writer suggests the combined switch and transformers of the type shown on Fig. 6 could be used to advantage. For instance, greater safety might be effected in the running of electric coal cutters by the use of such an arrangement at the gate end, whereby the coal cutter could be supplied at low pressure, say 100 volts. J represents transformers and switches for the lighting of roads of the type described above (*see* Fig. 7) The switches here would be set to trip out instantaneously on an overload of sufficient magnitude to be likely to be injurious to the winding of the transformer.

Conclusions.—The engineering advantages obtained by the use of electricity in mines are fully recognised, and fortunately the accidents from electrical causes have been very few in proportion to the accidents from other causes. At the same time it is true that the extension of this immense field for electricity depends very largely upon the freedom from fatal accidents. It is difficult to find any consolation for the remorse which follows the preventable loss of life; it is no use to call the victim of a mistake a "fool." To err is human, and the best-informed person is apt to make a fatal mistake in a moment of forgetfulness. It is, therefore, the best policy to encourage the design of apparatus which eliminates the risks, and in the long run this is also the cheapest policy, as it will be found that the substantial construction and enclosure of live conductors, whilst reducing risks, at the same time lessens the maintenance costs. It is gratifying to note how carefully the conditions appertaining to safety in switchgear designs are now considered in all quarters, and, given the necessary attention to the details on the other plant, including terminals on transformers and motors, the entire electrical installation can be made perfectly safe without extra cost in the long run.

The Progress of Electric Winding in England.

BY GERALD HOOGHWINKEL, M.I.E.E., M.INST.M.M.

Summary.—The points which are usually taken into account in considering the advantages of the steam, as compared with the electric winder, are low capital cost, simplicity and low cost of winding. As to capital cost, no general rule can be stated. If electric driving is being used for other purposes, there is not much difference in the cost of the two systems, even with a private installation; and with a public supply, the electric system is the cheaper. The exhaust steam turbine is now a factor in the case, but must not be pushed too far. Experience has shown that the less directness of the electric winder is not a disadvantage. The question of the cost of winding is one on which reliable information is not easily obtained, because the figures for steam are not readily separated. Costs are given for the electric winding plant of the Maritime Pit of the Great Western Collieries. In conclusion, the author describes briefly the different electric systems now available and gives details of electric winding plants in Great Britain.

The subject has been frequently treated, by the present writer as far back as 1905, when he read a Paper at Newcastle, which was afterwards re-discussed at a London meeting of the Institution of Electrical Engineers. Much progress has been made in this country since then, and many points which were carelessly brushed aside by mining engineers have now been established by actual results obtained by collieries at home. The object of the present article is to review the progress which has been made during the last few years, and to touch on a few points which may lead to a more rapid replacement of the wasteful steam winder by economical and handy electrical apparatus.

The points which were made over and over again on behalf of the steam winder were :—

1. Low capital outlay.
2. Simplicity, there being a direct application of the driving power.
3. Low cost of winding.

1. The first point is in reality the principal one, and practically the only one which is being considered by the colliery owner. Only the larger concerns, mostly limited companies, have recently adopted the electric winder, thereby following Continental practice. The fact that most of the collieries on the Continent are owned by limited companies with vast means has been the cause of the far more rapid progress of electric winding across the Channel.

The difference in first cost, however, between a modern steam winder and an electrical one is not as much at present as it used to be four or five years ago, and, if properly allocated, the total outlay for a new colliery with an output of, say, 3,000 to 4,000 tons, will be almost equal whether electric winding is used, or steam winding, taking for granted that all other plant will be run by electricity, with the exception, perhaps, of fan and air compressor, in the case of steam-driven winding plant. Of course, if electric power is obtainable from a power company, as is the case with a large new colliery the writer is connected with, the first cost of the all-electric colliery is even lower. Much depends on the locality, and the proportion of power required for winding, and for other purposes, such as hauling and pumping. A general rule, therefore, is impossible, and each case should be taken on its own merits.

The introduction of the exhaust turbine, however, has introduced a new factor, and its advent was seized upon by the advocates of steam winding, and, of course, also by the timid ones, as the saviour of steam winding by the one, and a step in advance by the other. The writer wishes, therefore, to utter a warning against the adoption of the exhaust turbine in this capacity, as its adoption in connection with new winding engines will only lead to disappointment, and discredit a most useful addition to our colliery equipment, with its proper customers. The exhaust turbine is an apparatus which turns into useful (mostly electrical) energy the wasted exhaust steam of existing non-condensing steam plant, but it is quite another proposition to create this exhaust steam to be used in a steam turbine, if its creation can be avoided. It is even more economical to use a compound steam winder and a live steam turbine for the electrical requirements than to put down a non-condensing engine exhausting into an exhaust turbine, the difference being about 5 to 10 per cent. in favour of the former combination.

In the outlay of a new colliery the exhaust or mixed turbine has no place, and it is the writer's opinion that not only will the capital charges be higher in the end, but also the running cost. They have, on the other hand, their very useful place in improving the efficiency of existing colliery plant.

The most unfavourable case for electric winding at first sight would appear to be in such cases where electric power has to be generated in a new power station, which should be started before sinking is commenced, but even in such instances a good case can be made out if one large turbine set is put down (as will be explained later) to provide power to supply the sinking engine motors, and also for the further requirements of the sinking, such as pumps, haulage (of materials), compressors. Later on, when the permanent winder is installed, a continuous-current generator can be added to drive the winder.

Point A.—Actual full load test over one hour.

No. 1, 7·48	units per wind,	12	per cent. load factor.		
No. 2, 6·60	"	"	16	"	"
No. 3, 5·61	"	"	19	"	"
No. 4, 6·13	"	"	16	"	"
No. 5, 5·70	"	"	21	"	"
No. 6, 5·69	"	"	22	"	"
No. A, 4·15	"	"	100	"	" for 165¾ tons =4·78 for 175 tons per hour.

The only way in which to arrive at a reliable conclusion, in the case of a new pit, is that of making a complete estimate of the capital outlay for power plant at the colliery (buildings included) on either system, providing plant in either case of a similar character as regards simplicity and accessories, and with an equivalent margin of spare plant included in each estimate. Where power can be obtained from a power company there is no question what the result will be; the all-electric system will come out the cheaper, as against the all-steam, or as against steam winding with exhaust steam turbines and the rest electric.

2. The second point has been for a long time the sheet anchor of the colliery engineer, and at each discussion the writer was asked how it was possible that electric winding could be more economical and reliable than steam winding seeing that there were dynamos, flywheel sets, cables and motors between the winding drum and the steam engine. The best answer to this is, if long arrays of figures are to be avoided, that it has been found to pay in every other application such as traction, rolling mills, factory driving, &c.

As to reliability, experience has shown that there are no grounds for increased apprehension. Electrical winding plants of all kinds have been running for some time without serious mishap. It is now quite practicable to make electric winding almost automatic. The colliery engineer is gaining knowledge of electrical plant, and the electrician is rapidly becoming a more responsible person. Electrical winding plant is also being immensely simplified; unnecessary appendages are falling into disuse and are being removed. In the case of the winding plant at the Great Western Colliery a flywheel equalising gear was supplied, and was in regular use for some months, but the colliery has since discarded it, with the concurrence of the power company.

Motors of a simpler construction are being rightly advocated. High-tension three-phase motors with their expensive windings are giving place to more robust low-tension machines, and electrical engineers are alive to the fact that simplicity and reliability must be achieved at all costs.

3. As to the cost of winding, this is a complicated calculation, and it is here that the staunch advocates of steam winding have gone hopelessly wrong. At the most the figures per ton of coal wound or per useful horse-power-hour in the shaft are hardly known or even guessed at. The few attempts to provide these figures from some of the best-known collieries in the north by a well-known advocate of steam winding have resulted in entirely misleading and incorrect figures. At best these figures gave an indication of what the steam

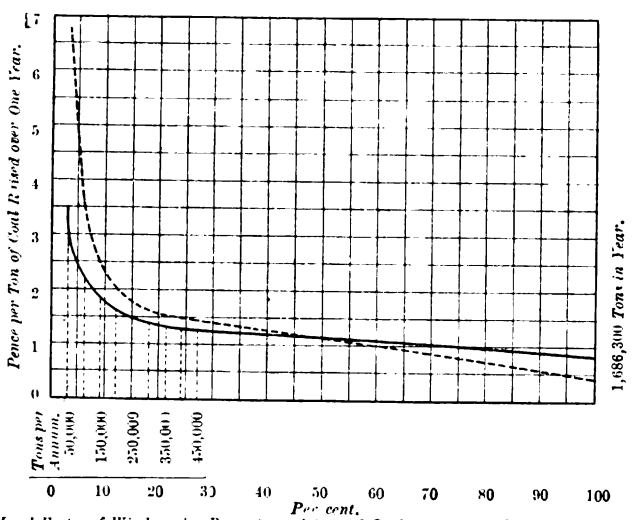

FIG. 2.—COMPARATIVE CURVES FOR STEAM AND ELECTRICITY, VIZ., FOR ESTIMATED COST PER TON OF COAL RAISED OVER YEAR FOR POWER ONLY.

consumption might be during the period of winding. But it is just here that electricity offers the all-important advantage that it does not waste energy during the time the machinery is idle.

What about the inefficient boiler house at collieries compared with a battery of boilers in a power station? What about the boiler and engine losses during the night, at week ends; in fact, during the 6,400 hours a year the plant is standing? These points were always forgotten by the steam men. On the contrary, with electric winding, these costs can be calculated in advance to a nicety, and at the Great Western Colliery, with which the writer is connected, the results have exactly confirmed the calculated figures drawn up in advance, and established a decided saving in cost over steam winding.

The results obtained with the electric winding plant at the Maritime Pit of the Great Western Collieries may be of interest, as this is the only electric winder in this country which has now been at work for two years and from which figures over a complete year are available.

The winder has been fully described by the writer in a former Paper, and it will be sufficient to say that it is on the Westinghouse principle with a light flywheel set in parallel which can be disconnected. The guarantee of the makers for a full load of 70 trips per hour was 4·8 units per wind with 17 tons of coal raised per hour. The influence of the load factor on this figure can be seen from the curves in Figs. 1 and 2, that in Fig. 1 giving the calculated curve and the actual results, and the curves in Fig. 2 giving the comparison between steam and electricity over a full year (1909) at various load factors. The steam curve has been carefully compiled from actual results at existing collieries drawing coal from the same depth and using good steam smalls at 7s. 6d. per ton. Electric power is obtained from a power company at about 0·6d. per unit, so that there is no doubt as to the cost with electric winding in this case. The curves have been prepared by Mr. H. Bramwell, the general manager of the colliery company.

The actual results during 1910 were as follows:—

Units consumed and paid for to the power company for winding only	448,000
Total number of winds of all sorts	122,724
Tons of coal raised	141,865
Tons of rubbish raised	65,512*

At 70 winds per hour the number of possible winds per year is 613,200, giving a load factor of about 20 per cent. The cost of power per ton of material raised is therefore slightly over 1d. and for coal alone about 2d. The costs of maintenance and repairs on the winding engine have been practically nil apart from oil.

The further advantages of electric winding may be enumerated briefly, as most of them are evident from the electrician's point of view and have been amply verified by the writer in actual practice.

1. The ability to run odd trips at any hour without the warming of the cylinders, &c.
2. More delicate control.
3. Less space is required for the winding plant, the motor being fixed on the top of the headgear if necessary.
4. Greater facilities for applying automatic protective devices.
5. Special shafts, for intermittent use at a distance from the main plant, are more easily provided for.
6. Steadier winding.
7. Power to control the acceleration.
8. Higher rates of deceleration are economically possible.
9. Heavy conical drums are seldom necessary.

DIFFERENT SYSTEMS EMPLOYED.

Many different electrical systems have been developed, which may be grouped under the following heads:—

(*a*) *Winding Motors (worked either by Continuous or by Alternating Current) connected direct to the Supply Mains without any Machinery for Equalising the Load on the Supply Mains.*—This system can be adopted where the maximum winding load is small compared with the whole output from the generating or sub-station. If a balance-rope be used and if the masses to be accelerated be not excessive, this system is often feasible. It has the two great merits of simplicity and cheapness, but is not always the most economical, as a large amount of energy is wasted in resistances. A good instance of the system is to be seen at the Harton Colliery, South Shields.

(*b*) *Continuous-current Systems with Batteries and Rotary Boosters.*—This system is, perhaps, entitled to rather more consideration than it has hitherto received. Where a continuous-current supply is available, it should not be lightly discarded. A great point in its favour is its undoubted reliability. If the winding motor be divided into two units and controlled on the series parallel system, as used for trains, there is practically a duplicate system throughout. It would always be possible to do a good deal of winding when any one item of the plant had broken down, even if that one were the main supply from the power station, and by adopting this system several winds could be made at any hour

* New workings opened up underground.

Digitized by Google

the day or night whether steam were available or not. The greatest objection to the system is on the score of cost, but this is being gradually reduced, and a reliable battery and booster plant can now be obtained for about £6 per electrical-horse-power. This figure, however, is excessive, if charged entirely against the winding plant, but it may be justified in some cases, when it would undoubtedly effect great economy in the whole power supply costs, particularly where exhaust steam turbines are in use. Agreements for the maintenance of the battery can usually be made with the manufacturers on quite reasonable terms.

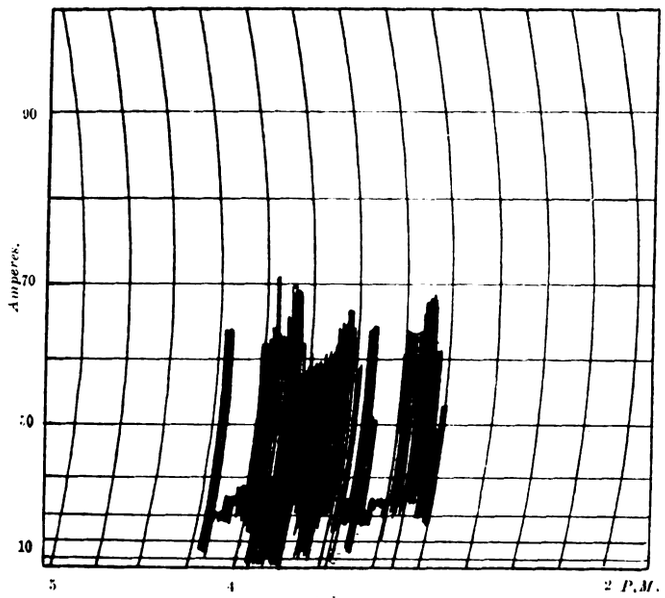

FIG. 3.—POWER COMPANY'S CURRENT RECORD DURING OFFICIAL TEST.
Readings × 0·8 = load at 11,000 volts.

(c) *System with Flywheel-equalising Machinery connected in Parallel with the Winding Motor across the Supply Mains.*—The best known example of this system is the plant erected at the Great Western Colliery, Pontypridd. Of those systems which make a constant demand on the power supply mains, it is probably the cheapest in most cases. A large portion of the energy goes direct from the mains to the winding motor, and the equalising machinery is only called upon to supply that portion of the peak load which is above the mean; therefore this gear need be neither so large nor so costly as that in the next system to be described. It also has greater claims to reliability, seeing that it is possible to wind without the equalising machinery. Another advantage, which will appeal to the electrician, lies in the better power factor which can be secured with this system. The disadvantages are: (1) The large current to be handled by the controller and (2) the inability to store energy in the flywheel during retardation, involving in some cases either conical pulleys, balance ropes or wasteful braking.

(d) *Systems in which the Winding Motors are driven entirely from Equalising Machinery.*—In this case the currents to be handled by the controller are very small, and great delicacy of control is secured. As little or no energy is wasted in resistances, the system is in many cases the most efficient. Energy can be restored to the flywheel during deceleration, so that there is more latitude in the design of the winding gear for a given output. In many ways the system is ideal from the electrician's point of view, except that each item of the plant is, as it were, a link in a chain, and failure of any one portion incapacitates the whole. It is also rather more costly in most cases than system (c). There are several examples of plant of this description in this country, and there will probably be more in the near future, both for colliery winding and for reversing rolling mills, owing to the verdict in a recent patent action in connection with the system.

(e) *Cascade System.*—This system is new, but is now being developed, and has some conspicuous advantages. The cascade motor may be described as two motors in one, there being two windings in the stator and two in the rotor. By manipulating the reactions of the two sets of windings on one another it is possible to run the motor at two different speeds without the use of any resistances; and at the same time, it possesses the property of the ordinary induction motor, of starting up with a large torque when resistances are inserted, with the advantage that only about half the energy is wasted in the process, whilst the torque is from 40 to 50 per cent. greater. There is a greater economy when braking, as the motor will act as a generator for part of the time, and return energy to the line. The adoption of this motor will undoubtedly improve the overall efficiency where the winds are short and the acceleration losses important. The power factor is high and the slip very small. The motors are also by nature specially suitable for low speeds, and have the advantage of being quite controllable when running dead slow. At low speeds they also possess the property of developing, for a given consumption of energy, a greater torque than at high speeds, so that the acceleration of the load is reduced automatically as speed is gained—a special advantage for winding purposes, as will be seen later. The cost of the motors is but little more than that of the ordinary type, and they should entirely remove the necessity for expensive equalising gears in most cases.

(f) *Continuous-current Motor supplied by a Combined Continuous and Alternating-current Generator.*—In this system, which has been worked out independently by the writer and Messrs. Brown, Boveri & Co., advantage is taken of the peculiar properties of large steam turbines, especially of the impulse type, as regards close speed regulation and large overload capacity. The turbine has coupled to it a three-phase alternator, which supplies the ordinary power load of the colliery, and also a continuous-current generator, the armature of which is permanently connected to that of the winding motor. The control of the winding is effected by varying or reversing the field of the generator, as required, on what is known as the Ward-Leonard principle. This system, therefore, embraces all the advantages claimed by system (d). The rating of the turbine should be suitable for the average load of the two

generators, the boilers forming the storage of energy. T... turbine runs at a high efficiency, with a fairly constant ... ing load, and provides the peak loads required for the ... with very little drop in either speed or efficiency. Th... cost of the plant is low, and there is less machinery to ... than with any other system. Where the winding load ... excessive, in proportion to the other power requirements ... the colliery, this is by far the most economical system ... supplying all the power needs of a colliery that has yet been devised.

The limitations of winding of any system seem to be reached between 3,000 ft. to 4,000 ft. on account of the large amount of coal to be lifted per wind, and the increasing weight of the rope. Although the rope makers are prepared to admit a lowering of the factor of safety hitherto adopted on account of increased quality, the advent of the electric winder has really been responsible for an all-round reduction in the figure, viz., from 8 to 5. This was due, of course, to the dynamic stresses being considerably reduced due to reduction of acceleration, even turning moment and decreased acceleration as speed increases.

It seems, however, that with increasing depths some other method of winding will be required, such as continuous winding with a bucket-chain, or pumping water and equalising coal wound by water, as is frequently seen with funicular railways.

With steam windings these limitations are sooner reached on account of the rapid increase in dimensions of the drums and engines. The electric motor, however, has enabled us to wind from greater depths on account of the permissible lowering of the static factor of safety of the rope and the fact that the limiting factor of the electric motor is the heating which is governed by the *average* speed and not the average maximum turning moment. These conditions may be still further improved by the use of a Koepe pulley and balance ropes, but for some reasons these have found no favour in this country, although they are largely employed on the Continent. The introduction of the Koepe pulley would considerably cheapen the first cost of the installation on account of the smaller masses which have to be accelerated.

The accompanying Table gives a list of the electric winders at present at work or under construction in this country.

NOTES RELATING TO THE TABLE.

I.—Great Western Colliery Co. (Ltd.), Maritime Pit.

The figures relating to the output and units consumed are the actual working results for the whole of the year 1909.

The weights include all the coal and rubbish raised, but no ... is made for the winding of men. It will be noted that the plant is capable of 70 winds, or 175 tons per hour. As the output (spread over whole year) only averages 23·8 tons per hour (exclusive of ...) load factor may be said to be only 14 per cent. When the ... raising 175 tons per hour, the energy consumed is 1·75 units ... giving a shaft efficiency 54½ per cent.

The capital cost of this plant was £7,450, or roughly £5 14s. per ... mum horse-power, equal to £31. 12s. per shaft-horse-power.

II.—Ferndale Colliery Co., No. 9 Pit.

These figures are taken from the published results of the test ...

III.—Powell Duffryn Colliery Co. (Ltd.), Abercwmboi.

The figures in this case relate to the average working ... plant, as run at full load. The winding motor is connected ... 3,000-volt mains without any equalising gear.

IV.—Great Western Colliery Co. (Ltd.), Cwm Sinking.

These figures relate to a proposed plant for this shaft, the ... of which, exclusive of buildings, but including flywheel, ... drum and shaft, with all accessories, is £19,000, equal to ... maximum horse-power, or £19. 5s. per shaft-horse-power.

The flywheel equalising set is required in this case, as ... large in comparison with the other requirements of the colliery.

V.—Mickelfield Colliery Co. and Etherley Dene ...

These columns give the estimated results of the plant ... under construction for these pits) when working at full load.

Coal Cutting.

BY H. J. FISHER.

Summary.—The author discusses the conditions under which electric coal cutting should be carried on to show success, and refers to some of the various types of machines that are at present available. Some references also made to the accessory apparatus connected with coal cutting. Finally a brief account is given of the chief electrical coal cutters at present on the market.

The mechanical cutting of coal was first heard of about the year 1761, when the first patent for this process was taken out by Mr. Michael Menzies, of Newcastle-on-Tyne. This patent was granted for a mechanical contrivance for cutting coal, which was to be driven by ropes or chains connected to a steam engine, or, as they called them in those days, a fire engine, or to a water-wheel or horse gin. It was not, however, until about the year 1870 that we hear of any real progress being made. The first machine to be driven by electricity was installed about the year 1887 at Bowers Allerton Colliery, in Yorkshire. The motor was not coupled direct to the machine, but was situated some distance away, power being transmitted from the motor to the cutter by means of ropes. Since that date electric coal cutters have made rapid advance, but have not up to the present caught up in numbers to their great rival, the cutter worked by compressed air.

Of late years great strides have been made with the art and practice of winning coal by mechanical means. Very great progress has been made in the use of machinery in mines, and in no branch has there been more progress than in coal cutting and conveying machinery. If a judicious choice be made in the first place, and sufficient care be taken with the maintenance and upkeep of the plant, still greater success will be attained.

There is no doubt that the winning of coal in the thin, and more especially in the deeper, seams will at no distant date be rendered a pleasanter and less hazardous task than it is at the present time. It should also, if the proper steps be taken, be a more profitable one for the owners.

The first thing to consider is the condition under which the machines will have to work, and the best methods of operation, so as to combine the maximum output with a minimum of repairs and upkeep. The success of coal cutting does not necessarily depend upon the number of yards cut by the machine on a certain day, but upon regular and systematic output. This can only be attained by a thorough, and at the same time expert, supervision, both on the part of the mining officials and the mechanical and electrical staff.

There are practically only two methods used for driving coal cutters, electricity and compressed air; of these two, electricity is by far the more efficient, being, in practice, three times as efficient as compressed air. The disadvantages of compressed air are greater initial cost, the trouble, owing to the movement of the ground, of keeping sound joints on the pipe system, and the greater cost of upkeep as well as the inflexibility of the system. The advantages are that it assists ventilation and that there is a great factor of safety from explosion.

The use of electricity in mines is regarded with some fear at the present time, but if proper care and attention were paid to details and good plant in the first place, and supervision were in the hands of a thoroughly reliable man, we should hear less about the possible dangers.

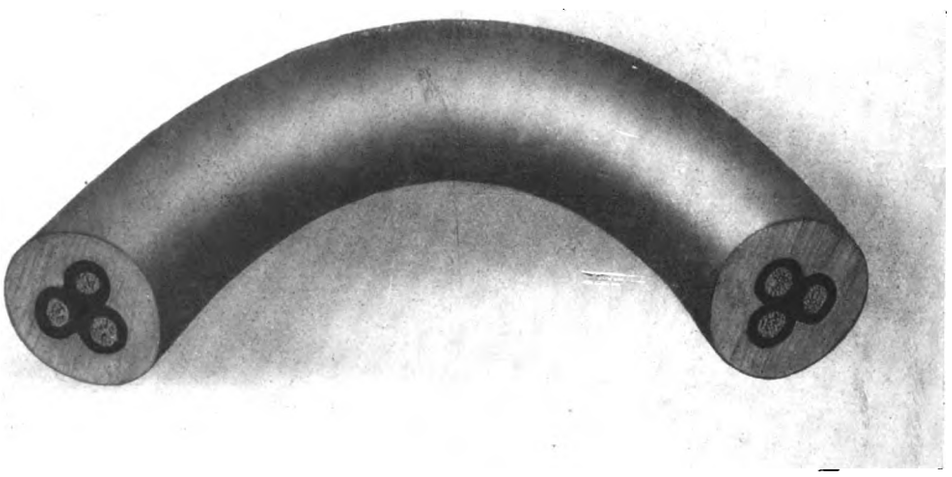

FIG. 1.—"CAB-TYRE SHEATHED" TRAILING CABLE. (St. Helens Cable & Rubber Co.)

Let us look into some of the dangers that may arise. Taking first the question of shock, this can be nearly eliminated providing that a proper system of earthing is carried out. In the old rules the earthing of portable machines was not compulsory, but in the new rules just issued this has been made so. In using the words "nearly eliminated" I was taking into consideration the fact that whatever rules may be drafted it is impossible to provide for the meddlesome or careless person, and this class of person has always to be reckoned with.

The next danger is that from sparking. This can be practically got over in the first place, for all modern machines can, without any great amount of trouble, be made perfectly flame-tight, a flame-tight joint being preferable to a gas-tight one. The word "gas-tight" is often misleading, as a joint may be gas-tight when new, but after a time the perishable nature of the material used for making the joint renders the apparatus practically useless against gas.

Cables are now made that are practically proof against external sparking, even under the influence of "dead shorts."

"Vickers-Ordnance" Mine Fan Ventilating a Colliery in S. Wales.

"VICKERS-ORDNANCE" MINE FANS

are unexcelled for high efficiency.

The construction is more rigid, and the wear on all moving parts is less in the "Vickers-Ordnance" Fan than in any fan of similar type; therefore the cost of upkeep is lower and the life longer than that of any other fan.

Gives greatest volume of air per revolution at all pressures, and

Maximum pressure is maintained, as the air does not slip back between the blades, hence the greatest possible efficiency is obtained.

Can be supplied for rope drive, or direct coupled to steam engine or electric motor, and

With Double or Single Inlet and fully or half-housed as may be desired.

Trailing cables are also made in the same way, the cores being insulated with vulcanised rubber and sheathed with bitumen and provided with a protective layer of tarred rope, this class of cable being made by Messrs. W. T. Glover & Co. There is also a new type of trailing cable which has been introduced by the St. Helens Cable Co. In this cable the cores are insulated with rubber and then sheathed with their well-known brand of cab-tyre rubber, as shown in Fig. 1. This class of cable is very light and flexible, and the makers claim for it distinct advantages over all other classes.

To adopt successfully mechanical means of cutting coal certain factors must be borne in mind. The choice of a machine depends mainly upon the nature of the coal, whether this is hard or soft, or if the machine is to cut in a band of stone, seggar or splint, for what may suit one seam will not suit another.

The choice may lie with either disc, bar or chain type of machine, and in all cases will depend upon the local conditions. For seams where the coal is hard and not likely to crumble and fall, the disc type of machine will best meet the requirements, or the chain type may be used. Where the coal is of a soft

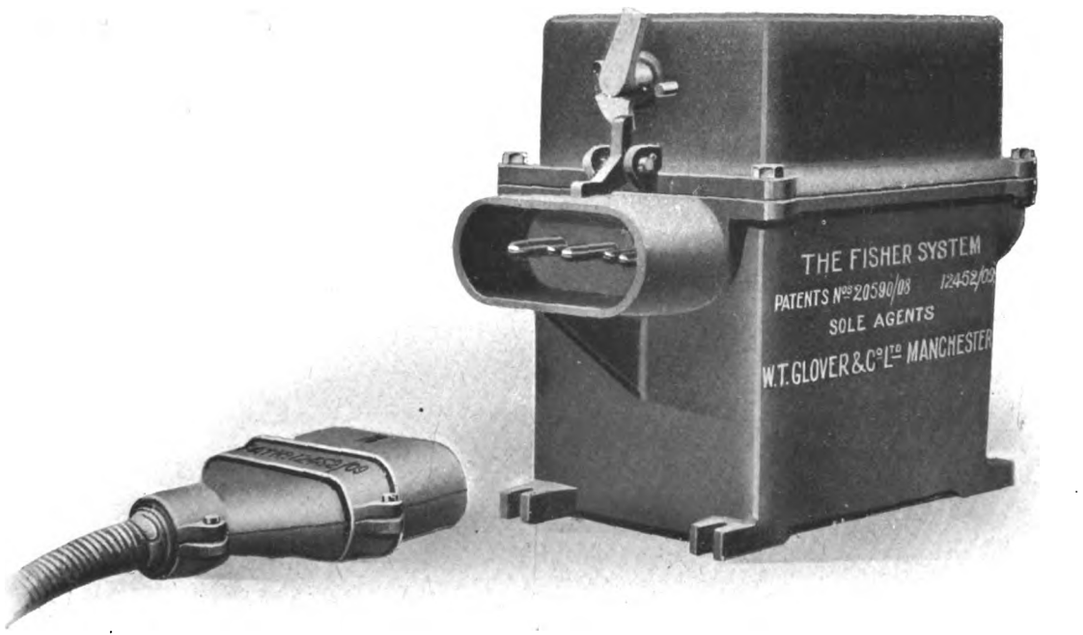

FIG. 2.—FISHER'S GATE END SWITCH.

There are now several excellent gate-end panels on the market; the switches for alternating current break under oil, and are flame and fool-proof. The plugs also are interlocked with the switch—a very desirable precaution indeed, as the plug cannot then be withdrawn unless the switch is in the off position.

A thing that is very necessary in connection with gate-end switches is that they should be automatic in action, and fitted both with overload and no-volt releases. The absence of fuses is a distinct advantage, as it obviates the necessity of the machine attendants replacing fuses (which is not a very pleasant task in the confines of the mine), besides preventing great waste of time; it also enables the switch box to be securely locked against tampering. Fig. 2 shows an ideal switch and Fig. 3 a diagram of the connections of the same, designed by the author, and embodying many important features which were described in our last mining issue.

and crumbly nature the bar type of machine will be most suitable.

Again, in choosing a suitable machine, care should be taken that it is not too light for the work to be done. Many coal cutters that the writer has come across have been far too light for the work they have had to do; in the majority of cases it has been principally amongst the minor details that this has occurred, but in some cases it has been the motor itself that has been too small for the work. For example, a machine sent out to under-cut 5 ft. 6 in. was found to be cutting only 20 yds.

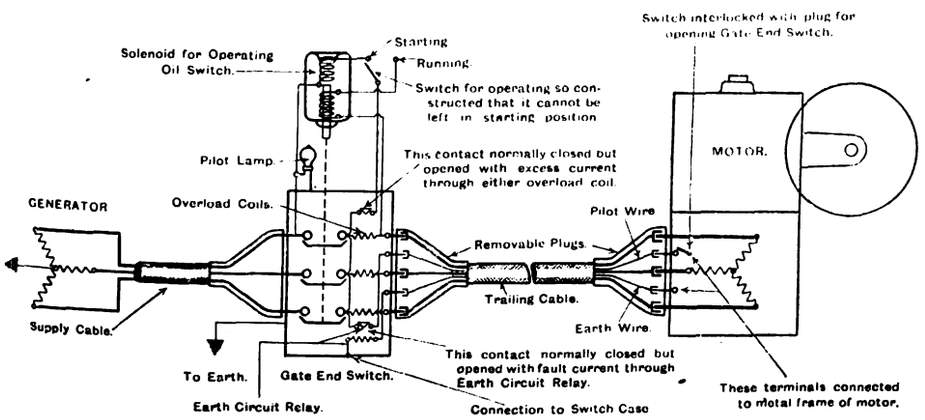

FIG. 3.—DIAGRAM OF FISHER'S GATE END SWITCH.

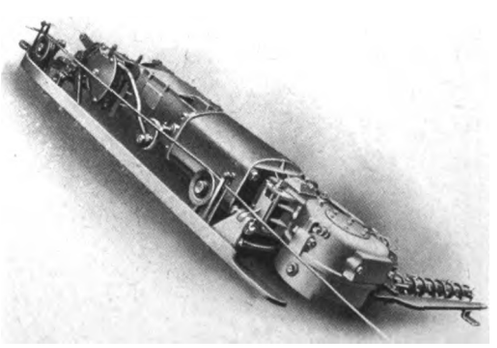

FIG. 4.—DIRECT CURRENT BEN COAL CUTTER.

to 30 yds. per shift of eight hours, and the troubles on the machine were endless. The cutting wheel or bar was changed, and the machine made to under-cut 4 ft. 6 in. Most of the troubles then disappeared, and, moreover, the machine has cut from 80 yds. to 100 yds. per shift.

As to the performance of coal cutters, the figures in Table I.

Digitized by Google

are results of tests, and Table II. is from data published by Messrs. Mavor & Coulson.

Table I.

Time.	Depth of under-cut.	Yards cut.	Units used.	Units per lineal yard.
2 hours	4 ft. 6 in.	40	12·0	0·3
3 hours	4 ft. 6 in.	60	20·0	0·33
1 hr. 54 min.	4 ft. 6 in.	35	11·9	0·34
2 hrs. 15 min.	5 ft. 6 in.	40	24·0	0·6
2 hrs. 20 min.	5 ft. 6 in.	45	25·0	0·55
1 hour	5 ft. 6 in.	28	15·5	0·55

Table II.—*Data by Messrs. Mavor & Coulson.*

Period of working.	Depth of cut.	Energy per sq. yd. cut.	Energy per ton produced.	Total cost d/d to haulage.	Previous cost by hand holing.	Saving by machine.
		Unit.	Unit.	Per ton.	Per ton.	Per ton.
One year.....	5ft. 3in.	0·53	0·35	2s. 5d.	3s. 11d.	1s. 6d.
One year.....	3ft. 10in.	0·26	0·24	1s. 8½d.	2s. 9d.	1s. 10½d.

One of the greatest drawbacks to coal cutting is the large amount of mechanical damage that occurs, but this can, to a very great extent, be overcome. There are three reasons for this trouble. Firstly, bad design; secondly, careless handling; and, thirdly, the absence of systematic overhauling of the machine and frequent inspection. In many mines there is a little too much of the haphazard spirit displayed in the inspection of machines, men being quite content to sit down and wait for trouble.

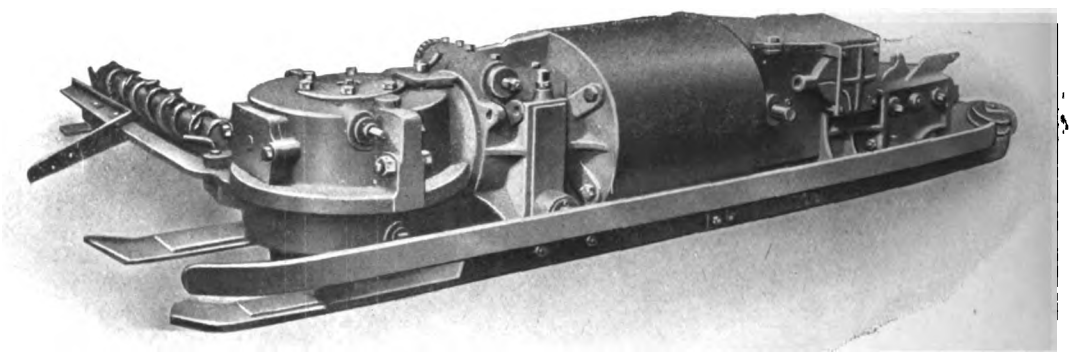

FIG. 5.—THREE-PHASE COAL CUTTER. (Mavor & Coulson.)

It has been found that the best practice, where the number of the machines in use would warrant it, is to employ a special man and to give him entire charge of both the mechanical and electrical parts of the machines. And to attract the right sort of man a good wage must be offered; it will pay over and over again.

Each machine at the beginning of each shift should be inspected, necessary adjustments made, and loose nuts and bolts tightened up. At stated and regular intervals whole machines should be brought to bank and thoroughly overhauled, a spare machine being kept to enable this to be done, and to prevent the loss of coal consequent upon a machine standing, or to prevent a machine being rushed back to work before the overhauling is satisfactorily completed.

Where coal cutters are situated considerable distances inbye, or where the use of electricity at the face is restricted, electro-air compressors have been introduced into the mine. These compressors are situated in an engine house in the main intake airways, some distance from the face. Such machines, however, work with a very poor over-all efficiency. In fact the power taken by the air compressor, just to keep the up pressure alone, has been found in practice to be as much as 45 per cent. of its full load. The power costs for cutting by these means work out at about six times as much as the costs of electric coal cutters. Notwithstanding the low over-all efficiency of the electro-air compressor, there is an ever-widening field for these machines; but the machines in use at the present time are principally small ones, and are chiefly used for supplying power to heading machines, pneumatic drills and percussive cutters.

It is very surprising how backward British mine owners are in adopting mechanical means of cutting coal, and this is found to be especially the case when comparisons are made with the number of machines in use in the United States.

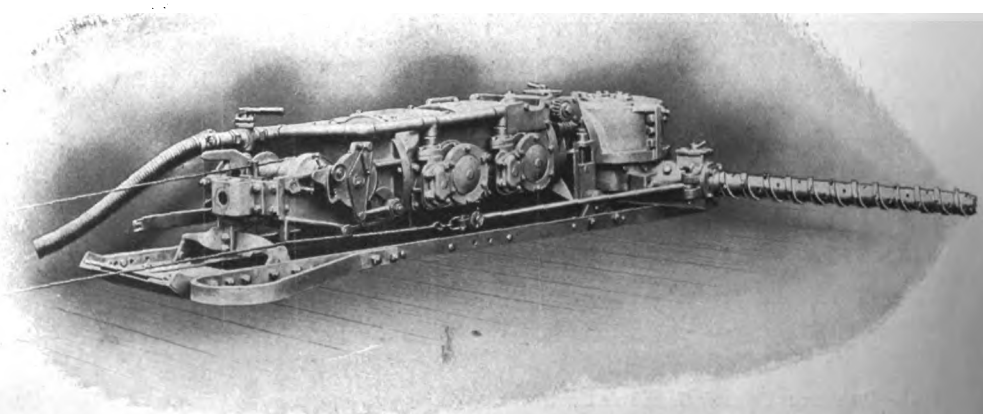

FIG. 6.—BEN TYPE CUTTER.

Taking the year 1901, there were 4,341 machines at work in the States and only 311 in Great Britain; in 10 years the increase in the number of machines in the United States was 3,796. Out of 3,000 collieries in Great Britain only just over

100 are using coal cutters, showing what a tremendous field there is for development in this branch of mining.

Seeing that direct current has been applied to coal cutters for about 24 years, it is not to be wondered at that the majority of machines are driven by this means. Alternating current has only been applied to coal cutters during the last eight or nine years. Alternating current has certain advantages over direct current, especially where squirrel-cage rotors are used, as there is less likelihood of sparking; but at the same time there is the disadvantage of the heavy starting current taken by this class of motor. This means that if fuses are used the machine has to be very heavily over-fused, and to get over this difficulty time limit automatic overload releases must be used. It is impossible to use a device to short-circuit automatically the fuses on starting, as these are situated some distance away from the machine, in the gate-end panel. If alternating current is used the author prefers a wound rotor, as by this means the majority of the starting troubles are overcome; very successful work is now being done by this class of machine. With direct-current machines the majority of the troubles are with commutating, and with short-circuits caused by the collection of coal and carbon dust.

Fig. 5 shows a three-phase machine of the well-known bar type invented by Mr. F. Hurd and manufactured by Messrs. Mavor & Coulson, of Glasgow. This type of machine is made in three different sizes to suit various requirements. In construction all three machines are the same, the coal being cut by a tapered steel bar, the cutting tools or picks being wedged into holes drilled into the bar; a spiral thread formed on the bar acts as a conveyor for the cuttings, and brings this dirt from the back of the cut. The bar fits into a socket which permits of bars of varying length being used. The socket for the bar, together with its gear, is carried upon a moving turntable which admits of the bar being swung round to any angle

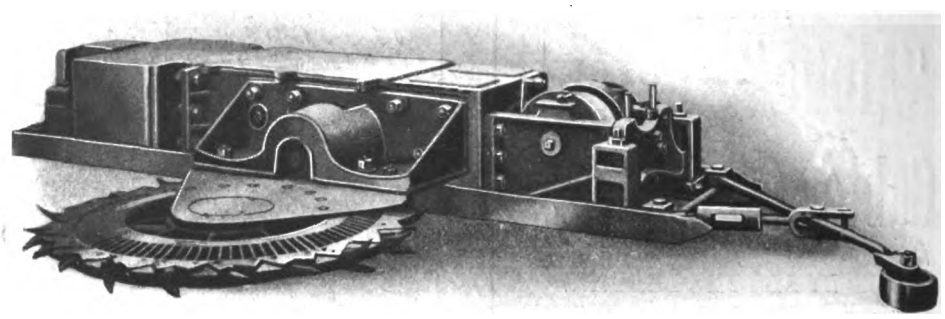

FIG. 7.—DISC TYPE COAL CUTTER.

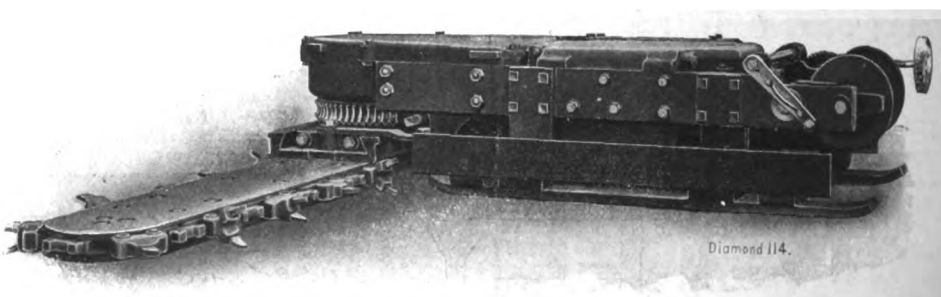

FIG. 8.—LONG WALL CHAIN MACHINE.

tilted up and down while at work. This arrangement allows the machine to cut at either side, and also to open up its own cut. The bar is run at a speed of about 500 revs. per min., a reciprocating motion being imparted to the bar as well as a rotary one. This produces a chipping or picking action, and is most effective when the machine is cutting in coal. The bar can be arranged to cut at floor level or above. The travel of the machine is arranged in exactly the same way as with the disc machines, by means of a haulage drum worked by a ratchet and pawl.

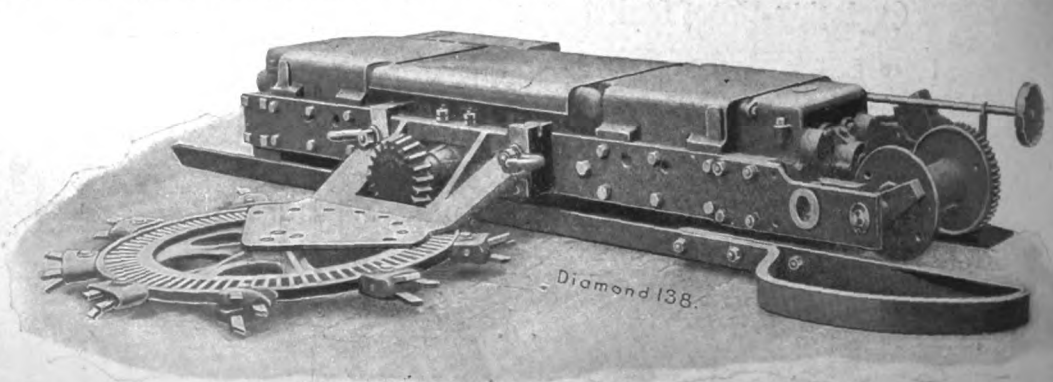

FIG. 9.—DIAMOND TWO MOTOR DISC MACHINE.

Digitized by Google

Fig. 4 shows a direct-current bar coal cutter, and Fig. 6 a compressed air bar-type cutter, both made by Messrs. Mavor & Coulson. Fig. 7 is a disc type of coal cutter which Messrs. Mavor & Coulson have recently put upon the market. This machine is called the Samson, and has been designed for cutting in very hard material. The machine is of great strength and rigidity, the working parts combining the essential requirements of strength and durability; ample protection is provided from injury from falling material, all parts are easily accessible and readily interchangeable.

Fig. 8 illustrates a long-wall chain machine which is made by the Diamond Coal Cutter Co., of Wakefield. This machine is made for both alternating and direct current. The jib carrying the cutter chain can be swung through an arc of 180 deg., which enables the machine to travel either to the right or the left. Great care has been taken to make the motors and switchgear flametight, the latter being fitted with safety devices to prevent accidents. Machine-cut gears are used throughout and are run in a steel case containing oil or grease.

Fig. 9 illustrates a standard Diamond two-motor direct-current disc machine. This is fitted with motors of 12 H.P. to 18 H.P., connected in series; the motors and switchgear are fitted in flame-tight cases, with the latest safety devices. There are more machines of this type in use than all the others put together.

Fig. 10 illustrates a standard single-motor direct or alternating-current disc machine, the motors ranging from 25 H.P. to 30 H.P. The alternating-current motors are fitted with ball bearings, and the larger size direct-current motors are fitted with four wound poles and ball bearings. The ball bearings are certainly a decided improvement upon the old type of brass or white metal bush. All the machines are fitted with special safety devices and automatic earth connections to comply with the new regulations; the plugs on the trailing cable are interlocked with the starting switch, by which means it is impossible to withdraw the plug and produce a spark while the machine is running.

Fig. 11 illustrates a standard pattern direct-current starting switch fitted with safety devices, the case being flame-tight and having machined faces 1¼ in. to 1½ in. wide; the lid slides into position and is interlocked with the switch, and cannot be opened while current is passing.

In connection with coal cutting, and more especially in thin seams, face conveyors are used, the best known type being the Blackett. This is continuous in its discharge, operating as it does by means of an endless scraper chain running along a U-shaped trough. The motors for these conveyors are designed to give 10 H.P. These conveyors are capable of delivering 30 tons per hour. A good roof and a rapid, and at the same time regular, advance of the face is an essential feature for the successful working of these machines.

Another type of conveyor is the Ritchie, which has an intermittent discharge. It consists of a belt 20 in. wide, and this is caused to reciprocate one-third the length of the face in a light steel troughing. The principle is something like a planing machine, in which the return idle stroke is considerably faster than the useful movement, thus avoiding needless loss of time.

Fig. 12 shows an interesting device made by the Diamond Coal Cutter Co. This is an earth leakage current release switch, in which the earth current passes through a fuse that holds the distribution switch in the "on" position. This is specially designed for the protection of circuits having coal cutter and other isolated motors which cannot be earthed other than through a practically insulated line.

Underground Colliery Wiring.

BY A. B. MALLINSON, A.M.I.E.E., A.M.I.MECH.E.

(Of Messrs. Mather and Platt, Ltd.)

Summary.—The author discusses the various points to which attention must be given to ensure a satisfactory system of colliery wiring, and he deals particularly with the selection of the cable, its handling, its erection in the shaft, the erection of in-bye cables, earthing, wiring for lighting and finally, the maintenance of the system.

General.—This subject is perhaps the most vital, and yet at the same time the most abused, of the whole of the links connected with the instalment of electricity in mines. Electrical appliances for underground use, *i.e.*, motors, switchgear, fittings and cables, &c., have now reached a high degree of perfection, and, provided they are correctly installed, and have reasonable attention given in maintenance, their safety, reliability and life will equal that of any other prime mover.

Motors and switchgear, being complete in themselves, can generally be relied upon when they are put to work underground to be in the condition in which they left the test-plate. With cables, however, everything depends on the way the cable is handled during erection, and the manner in which it is finished off. The possibility of trouble here is amplified by the practice, which is common in many collieries, of ordering the material from the various manufacturers, the instalment being carried out by the permanent staff at the pit, and so reducing the capital expenditure. It is under these conditions that the link known as the "wiring" is liable to suffer, and a few wrinkles on this particular branch of the work should, therefore, be of general interest.

To confine attention, three-phase equipments only will be considered, starting from the pit head. A typical wiring equipment of this kind is shown diagrammatically in Fig. 1. The subject can be divided up into eight sections :—

1. The selection of the proper type of cable
2. Hints on the handling of cable.
3. The erection of shaft cables.
4. Erection of in-bye cables.
5. The ends of cables.
6. Earthing.
7. Underground lighting wiring.
8. Maintenance.

1. Selection of the Proper Type of Cable.

For three-phase work all power cables would, of course, be three core. The insulating material can be :—

Rubber, by which it is inferred that the actual insulating medium is a combination of pure and vulcanised rubber.

Bitumen, in which the insulating medium is a non-hygroscopic compound.

Paper, in which the insulating medium is wrapped round the cable and impregnated with a hygroscopic substance.

Perusal of cable makers' lists will show an amazing variety of cables, but they all boil down to one or another, or a combination of two of the above.

Rubber is practically out of court for three-core cables on account of price, its use now generally being confined to trailing cables, where great flexibility and tenacity of insulation is essential and for small single-core cables. The word "rubber" (like the actual article) has a most elastic meaning, and the purchase of this class of cable for underground use must, therefore, be effected with great care. While for insulator wiring in workshops, &c., above ground, a cheap grade of rubber cable is undoubtedly quite reliable, the risks underground are obviously such that none but the best quality of material should be permitted.

Turning to bitumen and paper insulated cables, the relative good points can be got from any manufacturer's list. The question for the mining engineer is, "Which is the best for colliery work?" While paper-insulated cables have, in certain collieries, been successful, even their most rabid supporters must admit that they are essentially an electrician's cable, and require the most careful handling by expert jointers to ensure satisfactory installation.

The main objections raised to bitumen cables are :—Liability to decentralise, and low insulation tests. With the even temperature underground (when electric power is used), decentralisation, provided the cables are not excessively loaded, may be ignored. Low insulation tests are not fatal to the working of a plant, and, for the general run of colliery requirements, they cannot be said to be such as to preclude the satisfactory use of bitumen cable. If, however, this is objected to, one of the combination cables can be used, whereby the insulation resistance will be doubled or trebled. In this connection, a cable made of a combination of rubber and bitumen, *i.e.*, both non-hygroscopic materials, known as "reinforced bitumen," which is now being put on the market by one of the leading firms, should be of value for colliery use.

The factor of safety of any wiring system is dependent upon the number and workmanship of the joints. It is here where the hygroscopic cable is liable to fail. The bitumen (or non-hygroscopic group of cables) are therefore recommended as the most reliable all-round cables for mining purposes.

2. Hints on Handling of Cables.

While bitumen cables are, generally speaking, of robust construction, they require a reasonable amount of care in handling.

If possible, the cable should be taken to its site on the drum as received from the maker's.

Don't handle the cable above ground in frosty weather as the bitumen is then brittle.

When lifting up the end of a cable, never let it fall, but lower it gently to the ground, otherwise the bitumen sheath may be shattered, and sooner or later cause a failure.

No three-core cables should be bent round a diameter less than 20 times the diameter of the actual cable.

Particularly watch for kinks in erecting the cable.

In preparing the ends ready for jointing, do not force out the three cores unduly from the centre. If this is done there is considerable likelihood of fracturing the insulation where it leaves the solid worming.

3. Shaft Cable.

For shaft cables, the type recommended is a solid bitumen core, double wire armoured, canvas or jute served (see Fig. 2).

At the pit head the cables should be brought out well away to avoid any possibility of fouling by the winding ropes when new ropes are being lowered down the pit. Fig. 3 illustrates a common way of carrying the cable away from the shaft head, and shows also the type of suspension to take the vertical weight of the cable. In the shaft itself, the position for fixing the cable should be selected where the cable will be most out of the way and least liable to damage by any falling material out of the pit cages.

For three-core cables, supports every 40 to 50 yards are advisable, a good construction being shown in Fig. 4, which is a support for a 0·2 sq. in. three-core 2,600-volt solid bitumen cable, taken about 400 yds. from the surface. The smaller leads shown in this photograph are respectively signalling and low-tension lighting cables.

The erection of shaft cables is a comparatively simple matter, provided it is undertaken in the right manner. There are two ways in which it can be done :—

(*a*) To sling the drum below the cage, and lower out the cable, cleating it as the cage is lowered. In this case there should be a loop of cable hanging below the cage as a safeguard. This is only applicable where the shaft is sufficiently large to take the drum.

Digitized by Google

(*b*) To lower the cable from the surface, suspending it as it is lowered by clamping it temporarily to a wire rope about every 30 or 40 yards, leaving the cable slack between each clamp so that the weight is taken on the wire rope. After so lowering down, permanent clamps can be fitted.

If the latter method is adopted, be careful to have all appliances at hand before starting. Mount the cable drum on trestles, and provide a means for breaking it as the cable is drawn off. Operate the tension rope from either a steam or hand winch, in either case having good brakes. Anchor everything securely, and above all don't skimp the labour available. Three or four pounds wasted here is nothing compared with the loss that would occur if the cable overcame the men and went down the shaft.

At the bottom of the shaft bring the cable into the workings with the minimum of horizontal length actually in the shaft. Every foot of cable in this position is more liable to damage from falling material than 100 yards of vertical cable.

Immediately after erection the whole of the shaft cables and suspenders should be well treated with Stockholm tar.

4. Erection of In-bye Cables.

For fixed positions underground "Three-Core Bitumen Single-Wire Armoured and Served Cables" are most suitable. Where flexibility is required, such as for coal cutters, heading pumps and the like, a "Rubber Insulated Four-Core Hard Cord Braided Cable" makes the best job, the fourth core being used for the earth connection. For the erection of in-bye cables no hard and fast rules can be recommended. Everything depends on the nature of the roof, the facilities underground for erection, class of mine, and size of cable.

For main roads close to the shaft bottom, if brick walls and reinforced concrete roofs are used, the cables may be supported on bearers built into the brick-work. Further from the shaft, in the actual workings, to comply with the Mines Regulations, flexible suspensions are necessary. The old raw hide suspenders are hard to beat in this way, provided they are put in of sufficient size to carry the weight of the cable and not pitched too far apart. Canvas suspenders are also good, particularly those which are made with a wide base to distribute the load on the cable. Spring clips have not made much headway, and can hardly be said to be commercially practicable for any but the driest mines. The support for the cable can easily be taken from an ordinary pit nail driven into the timbers, or, where such do not exist, into a plug in the side of the road.

In running power cables down dips on suspenders it should be remembered that the ordinary leather thongs are not well adapted for taking the weight of the cable on a dip, and provision ought, therefore, to be made every 30 or 40 yards to anchor the cable.

The getting of cables in-bye is, with larger sizes, often a matter of considerable difficulty. If the roads are big enough the cable may be unwound going down the road, being cleated up immediately behind it. If, however, as is often the case, a cable drum cannot be got down the workings, it will mean handling by hand, and here again the importance of ample labour should be emphasised. Five or 10 years can easily be taken out of the life of a cable by dragging it along the roads with blocks and tackle, whereas, with sufficient labour, it could have been carried down and thus ensured freedom from damage.

5. The Ends of Cable.

To an inspector on the lookout for safety of a system, the ends of the cable are points which immediately attract attention. It is no use having highly insulated cables if care is not taken where the armouring ends to protect in some way the single conductor leading to the switch or motor. This point is where wiring underground has been liable to develop weakness. The illustration in Fig. 5 is a typical example of the way in which

connections up to the machine from the switch are sometimes left exposed and liable to damage.

To any engineer wishing to know whether his system is sound, the writer would say "examine the ends of your cable."

The obvious remedy for this weakness is, if possible, to do away with exposed ends of cables, *i.e.*, by running a three-core armoured cable right into the motor or switch or whatever it is to connect up to. With switchgear this is now generally being provided for, and it at once eliminates one of the prin-

cipal weak points. At the motors, however, the case is not so simple as it would at first sight appear. The temperature rise of the motor during running may be such as to liquify the com-

pound in the trifurcating box if this is actually fixed to the motor. For this reason, mainly, few engineers recommend the fixing of trifurcating boxes actually on the motor frame.

If there must be an exposed length of unarmoured cable, then it is a good policy to use, for the rubber tails, cord braided cable. This class of cable is soundly protected mechanically and makes a much better job than the ordinary rubber tails taped and braided.

The use of trifurcating boxes is, of course, essential on high-tension wiring systems, but for 500-volt and lower pressure equipments, there is, with bitumen cables, no need to use a

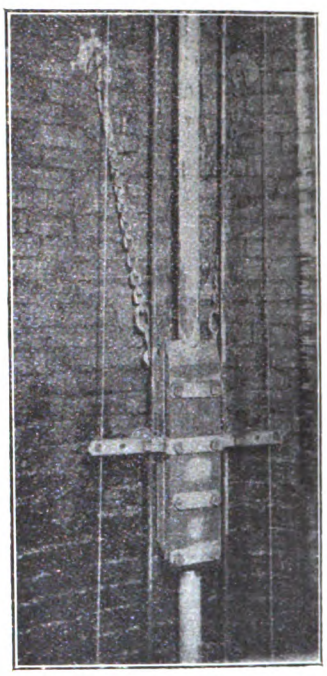

FIG. 4.—1,000 H.P. HIGH-TENSION CABLE SUSPENDED IN SHAFT, ABOUT 400 YDS. FROM SURFACE.

dividing box, provided the cable is made off in a suitable manner. A method adopted for this class of work by the writer's firm for many years has been to bend over the armouring and bind it back, as shown in Fig. 6, the three bitumen cores being separated, taped with Empire tape, and then the whole tightly bound with whip-cord braiding from the armouring right up to the ends of the single cores.

The use of sleeve terminals is now becoming very general among makers of electrical machinery. While they make a good electrical joint, and are neat when installed, they are liable to produce a risky point in the installation unless care-

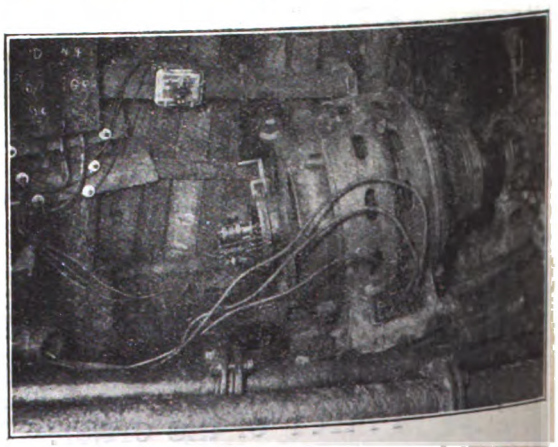

FIG. 5.—AN EXAMPLE OF RISKY WIRING UNDERGROUND.

fully guarded. The general principle is to tape over the terminal after it has been made permanent, which gives a perfectly sound job. This, however, is liable to prove a weak spot if the machine is disconnected (say for testing), as it does not always follow that the electrician has suitable tape with him to remake the joint. Terminals, therefore, which have a

Digitized by Google

loose rubber or other sleeve which can be easily bound over the bare portion and so insulate it, are preferable.

6. EARTHING.

Considerable stress has been laid by the Committee investigating the conditions of Electricity in Mines on the importance of sound earthing, and the alterations in the proposed new rules will be drastic in this respect. Earthing, in the past, has certainly, in too many cases, been looked upon as a sort of afterthought, and carried out in a very unmechanical, and certainly unelectrical, manner.

It is not sufficient to leave it to the discretion of the wireman how to attach his earth connections on to the machine: there should be a proper earthing terminal fixed for this purpose. All earthing must start from the surface. There ought to be at least two earths there, both connected in a sound mechanical manner to the armouring of the shaft cable. In-bye the armouring of the cables can be used for earth purposes, but it must be remembered that every joint in the armouring is liable to add resistance to the earth return, and, consequently, the fewer there are the better. Every care must be taken in making off the armouring to ensure a good metal-to metal joint. It is safer to bond from armouring to armouring with a stout copper earth connection and carry from it any earth wiring required to the machines at that point. The practice sometimes adopted of earthing one machine on to the other in series is bad. There is too much risk of a bad contact and increased resistance in the earth

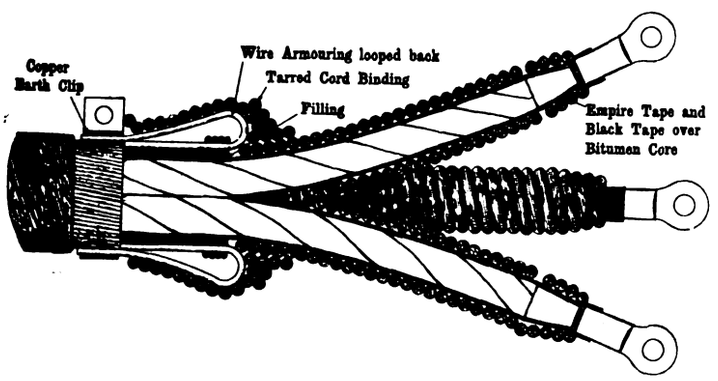

FIG. 6.—METHOD OF MAKING OFF BITUMEN INSULATED CABLES UP TO 500 VOLTS.

connection. Also, any possible removal of an earth wire for a short time disconnects the whole of the remaining equipment further in-bye.

The section of all earth wires should be such as to carry easily the overload current of the machine to which it is connected without any possible danger of fusion.

7. UNDERGROUND LIGHTING.

Electric lighting underground requires as much consideration as power wiring to ensure safety. Many systems have been proposed and tried, with varying degrees of success, but the general trend of opinion appears to be that the simplest systems are turning out the most reliable and safe in practice. The writer recommends insulator wiring absolutely. Pipe wiring is of no use whatever underground. The pipes rust, condensation occurs, and in few cases can one guarantee that the wires when they are in a pipe are in the condition they are supposed to be. On the other hand, insulator wiring, provided it is done on the right lines, is easily put up, and always in view, and therefore, under inspection.

Guarded fittings should always be used with the lamps, surrounded with a water-tight well glass as a protection against mechanical damage. A convenient way of fixing these to the pit timbers is to carry the water-tight bracket fitting on a "U" iron frame, about 2 in. from the timber, so that the wires themselves can be looped into the pipe and out again. The wires can be supported on the usual porcelain insulators, pitched about every 8 ft. They should, of course, be kept as far apart as underground conditions will allow. For lighting wiring, cord braided cable is recommended as giving a greater mechanical factor of safety than is provided for in the ordinary taped and braided cable.

The voltage of supply should be kept down, on no account exceeding 100 volts. It is far better policy to keep to low voltage and put in small step-down transformers in the motor rooms adjacent to where light is required. The lower the voltage on the lamps, the bigger the factor of safety all through for lighting. For this purpose, 25-volt lamps should always be borne in mind for the lighting of in-bye machine houses, &c., where it is not necessary to light over any extended area.

Where lighting through step-down transformers, it is advisable to earth one side of the system as a safeguard against any failure of the transformer. Lighting through transformers underground in this manner will, of course, entail the use of leakage indicators for each circuit, which, however, can be fixed in the machine houses and read by the men in charge, in accordance with the Regulations.

8. MAINTENANCE.

Having once installed the equipment, a systematic maintenance, which need not be expensive, will ensure it being kept in good order. All cables underground ought to be treated every two or three months with Stockholm tar as a preservative. All earth connections should be checked each week when the insulation tests are taken of the equipment underground. The main earth points above ground are the most important of all. The fact that they are out of sight must not allow them to be out of mind. If the earth is made into water, particularly watch the wires leading into the water to see that they are not corroded through.

Do not countenance any temporary wiring, for if once allowed it may become a regular thing, and introduce a weak link into the system.

Take in hand at once the slightest defect reported. A whole length of cable can easily be ruined through allowing a fault to go too far.

To summarise the whole matter of colliery wiring, the importance of using the best materials installed in the soundest manner cannot be over-estimated. A few pounds saved in the installation can be lost many times over by the most minor trouble which could occur in a colliery wiring network.

Recent Extensions in the Yorkshire Electric Power Co.'s Supply to Collieries.

Among recent extensions of the Yorkshire Electric Power Co.'s supply to collieries we may mention several interesting installations. These include the Micklefield Coal Co., who are sinking a new pit at Ledston, where it is proposed to use electric power throughout. The winding machinery is of the Ilgner type. The screens will be situated some distance from the pit near the Company's Peckfield Colliery, and these and other machinery at the older colliery will also be operated electrically.

The New Silkstone & Haigh Moor Co., at Allerton Bywater, are using the power company's supply for a great variety of purposes, including two underground winding gears, haulages, pumping, screens, washer and other machinery. Extensions are being made by the installation of an electrically-driven air compressor.

The Old Silkstone Collieries, who are erecting a battery of 80 by-product coke ovens, are under agreement to supply the waste heat from these ovens to the power company. Their existing electrical machinery will be driven from the power company's supply. The large washery and screens which are being erected adjacent to the coke ovens will be operated electrically, and also a considerable amount of pumping and haulage at the Dodworth, Higham and Stanhope pits.

Electric Hand Lamps for Collieries.

BY WM. MAURICE, F.G.S., M.I.E.E.

Summary.—The author first considers the use of electric lamps, as now compulsory, for rescue purposes, and then discusses the desirable qualities in a lamp for ordinary mining use. Figures of cost are given and it is pointed out that a fire-damp detector is not an essential adjunct of such a lamp.

The production of a satisfactory portable electric lamp has been the aim of numerous inventors ever since electricity began to have commercial possibilities. Designs comprising the use of both primary and secondary cells have been evolved in hundreds; many have never passed beyond the "paper" stage; most have had their little day and disappeared; few, if any, have come to stay. At intervals of a few years there is a revival of interest in the subject arising either out of the appearance of a new and apparently promising lamp, or by reason of the undoubted demand calling more urgently for that supply which it is supposed to bring forth.

Some such urgent demand now clamours to be satisfied, but unless the writer's experience of hand lamps, even though it spreads over the past 20 years, has failed to bring him into touch with some improvements of sound practical value, it is difficult to imagine that the era of electric hand lamps has yet arrived. It must be admitted that it is now possible to obtain portable lamps in great variety and of ingenious construction which are fairly satisfactory for individual purposes.

The great field which awaits development is, however, in colliery and mining applications, where the necessity for improved illumination is slowly coming to be recognised as one of the three primary conditions of safety.

Demand has also been accelerated by recent specific recommendations, culminating in an Act of Parliament which will make compulsory the provision of electric hand lamps for certain purposes.

Since the occasion referred to is the first, probably, in the history of electric lighting—certainly the first in the history of electric hand lamps—upon which the provision of such apparatus has taken the form of a definite legal obligation, it may be useful to ascertain precisely what the law requires.

Electric Hand Lamps for Rescue Work.

In October, 1910, a committee, known as the Mines (Rescue and Aid) Committee, was appointed by the Home Secretary to consider the organisation of rescue and aid in cases of accidents in mines. This committee held four meetings and on Feb. 8, 1911, submitted the draft of an Order which they recommended should be made under the Mines Accident (Rescue and Aid) Act, 1910. The Order, after specifying the numerical strength and conditions of training and qualification of rescue brigades and determining the provision and maintenance of portable breathing apparatus at every mine, proceeds with the condition, among others, that "there shall also be provided and maintained at every mine . . . two electric hand lamps for each brigade, ready for immediate use and capable of giving light for at least four hours."

In addition to this rule for the provision of two lamps at every mine, "there shall be kept and maintained in every Central Rescue Station . . . 20 electric hand lamps."

It will thus be seen that whether electric hand lamps have reached a satisfactory degree of perfection or not, mine owners are compelled to obtain a definite number of them and see that they are kept in usable condition.

Observing that the Order also requires the provision and maintenance of "a safety lamp for each member of the rescue brigade for testing for firedamp," it may be presumed that the committee have recognised that there is not yet any electric hand lamp which carries an entirely satisfactory device for indicating the presence of firedamp.

The requirements attaching to the use of electric hand lamps for the use of rescue brigades differ to an appreciable extent from those which an ordinary miner's lamp calls for—the principal points of difference being in the degree of intensity of light and in its duration. Rescue lamps are not required to supply light for so long a period as miners' lamps—it will have been noticed that a four-hour lamp is specified in the Order—but the light must be as brilliant as possible, and, although the Order does not say so, it is obviously a fundamental necessity that the lamp should undergo no diminution of brilliancy whilst in use.

Very exhaustive experiments have been made at Camphausen, in Germany, for the purpose of determining the reliability and duration of various types of lamps designed for the use of rescue brigades. A few notes on these tests, which were specially directed to the choice of a lamp suitable for working in an atmosphere of combustible or unbreathable gases, firedamp and after-damp, may advantageously be taken from Herr Rossenbeck's report, for the use of English designers who may perhaps not be fully conversant with the difficulties which have been experienced in practice.

The principal requirements are summarized as follows:—With the greatest possible brilliancy and duration of light the ideal lamp must combine the least possible weight. Its size and circumference must be such as to permit of easy handling; wherefore projections and sharp angles are to be (as far as practicable) avoided.

The switch arrangement must so work that there is no possibility of ignition in gaseous mixtures by means of an initial or terminal spark.* The same consideration should also be borne in mind when it becomes necessary to screw on a fresh lamp bulb. The entire structure of the lamp must be such as to enable it to withstand unalterably the rough usage to which it will be infallibly subjected in the course of everyday work down the pit.

The first experiments were carried out with a couple of Richter lamps which took 12 hours to charge and discharged continuously for eight hours.

It was found that these lamps might be allowed to stand unused for eight days after charging without the duration of illumination being thereby affected. But for any more lengthy period a marked decrease in duration was observed, becoming more marked as the interval between charging and use was extended.

The lamps were tested in conjunction with the pneumatophore breathing apparatus and proved unreliable and unsuitable for use in the pit. The same makers thereupon brought out another lamp which differed from the earlier pattern in the arrangement of the accumulators and the incandescent lamp bulbs. It was also of smaller dimensions and lighter to carry and special care had been taken to secure easy interchangeability of parts.

The trouble with this one was that which English, and in fact all, makers of hand lamps have found so hard of solution, namely, the difficulty of preventing oxidising or incrustation of the switch and other metallic parts owing to the action of acid and acid vapours escaping from the cells of the accumulator.

Accordingly, a dry accumulator weighing about 6 lb. and burning 10 to 15 hours was tried, but these were found to deteriorate after storage for a year or two. It was further reported that in the course of the drilling of rescue classes, setting up dams against fires, and similar operations, the lamps had proved very unequal; some burnt well, while others would not burn at all.

Trials were next made with the Adolf-Bohres lamp (which was exhibited in England a few years ago). This was one of

* In this connection a useful note by Mr. R. Nelson, H.M. Electrical Inspector of Mines, will be found on p. 27 of the Official Report (Cd. 5824) on the Causes of and Circumstances attending an Explosion or Underground Fire which occurred at the Wellington Pit, Whitehaven Colliery, on the 11th May, 1910.

Digitized by Google

the earliest lamps to be fitted with an osmium filament, the introduction of which rendered possible the production of single-cell accumulator lamps. The makers of this lamp, and indeed almost every maker of portable lamps, hailed the application of metallic filaments as though it had finally solved all hand lamp problems, but the old corrosion trouble again blocked the path of progress. Later research has resulted in the production of a metal alloy on which diluted sulphuric acid has only a small and slow effect, but, next to the usual internal troubles with which all users of storage batteries are familiar, this question of terminals and contacts remains the most difficult of solution.

HAND LAMPS FOR MINERS.

First consideration has been given to the production of a rescuer's lamp because this represents an actual and immediate demand. Many of the British rescue stations for which they are required are already built and equipped, while several others are now in course of erection. The total requirements for this purpose are numerically negligible, although it is probable that at least 3,000 lamps will be required.

This figure, although doubtless satisfactory to lamp makers, who have hitherto sought in vain for extensive markets, pales into insignificance when compared with an estimate of the numbers which would have to be produced if it were possible to oust the gauze capped safety lamp from British mines. There are over 600,000 safety lamps in daily use in this country, and there are some 1,700 mines (employing two hundred odd thousand persons), where naked lights are yet in use, but which will no doubt require hand lamps at no distant date.

Out of the 600,000 lamps in use, not more than 3,000 are electric lamps, and these are confined practically to the two mining districts of Durham and Liverpool and N. Wales.

The Murton Colliery installation, where 500 lamps were put to regular work in October, 1897, and the number made up to 1,000 by October, 1899 (and 1,200 in 1902) is probably the earliest instance of the use of electric hand lamps in mines on a practical and fairly extensive scale.

The Sussmann lamp was then in use and cost 18s.

The cost of working the lamps over a period of several months, including all charges except interest on capital and the cost of running the dynamos, was stated in a Paper read before the North of England Institute of Mining and Mechanical Engineers (Trans. I.M.E., Vol. XXII, 1900-1) to be as follows :—

All labour, at basis rates, including superintendence, cleaning, making ready, maintenance, &c.	2·19d.
Material for renewing batteries, repairing and maintaining the lamps in every part, and lamp glasses	1·00d.
Lamp bulbs	0·60d.
Total per week	3·79d.

The life of the battery was stated to average 10 months.

By 1903 the number of lamps at Murton had been increased to 1,400, and the cost was then stated by Mr. W. O. Wood to be about 3s. per lamp per annum more than that of the ordinary oil lamp.

It is thus seen that since one colliery can by now account for more than half the total number of electric lamps used in Great Britain, the present field of application is exceedingly limited. The reason for this is twofold. In the first place the charging and repair of hand lamps on a large scale is very troublesome, except, perhaps, as in such instances as that which has been quoted, where the use of electric hand lamps has been specialised. In the second place the capital outlay on an average installation—say 1,500 lamps—is so far in excess of the cost of ordinary safety lamps that few colliery companies will be found prepared to incur the additional expenditure unless there are special local reasons for doing so. The cost of renewals too is ordinarily excessive and there being no immediate prospect of radical improvement in this respect the only way of reducing this important item is to use a smaller battery.

It is very probable indeed that it would "pay" to expend the extra amount, because increased illumination would tend both to enhance the individual efficiency of the workers and to lessen the number of accidents; but the majority of mine owners are not sufficiently enlightened to understand that money may be frequently saved by judicious spending.

If lamp makers wish to extend the use of electric hand lamps in mines—and the writer ventures to assure them that in so doing they will be promoting a very important advance in mining practice—it is necessary that they should design lamps which can compete on as nearly equal terms regarding costs as possible with the ordinary safety lamps which are in use to-day.

The ordinary safety lamp is supplied to collieries either by outright purchase or on a hire or hire-purchase basis.

The outright cost of a safety lamp varies with the make but may be placed at 6s. to 7s.—say an average of 6s. 6d.

On a hire-purchase basis lamps may be obtained at from 5¾d. to 6¼d. per lamp per month, including oil, wick, repairs and renewals. The lamps become the property of the colliery company after a period of five years.

Some exceedingly useful figures, which may be taken as representative of good colliery practice relative to the cost of lighting by safety lamps were given by Mr. J. P. Kirkup at a meeting of the National Association of Colliery Managers in October, 1908. A test was carried out on "Marsaut" type lamps electrically lighted and locked, with a mineral oil having a flash point of 300°F., weighing 8·25 lb. per gallon, and costing 7½d.

It was found that one quart filled 14 lamps, and that each lamp so filled burned 20 hours. Assuming that each lamp is burned for the full period of 48 hours per week, then, since (14 × 20) 280 lamp-hours cost 1·93b. one lamp burning for 48 hours costs 0·332d. per week.

Lamp wick is consumed at the rate of 12 yards for 750 lamps in 14 days at a cost of 5d., making a cost per lamp (for 48 hours) week 0·0028d. The cost of minor repairs is taken at one-half of a man's time on 750 lamps, at 30s. per week, equal to 0·24d. per week.

Charging batteries (used to operate the lighting up and locking apparatus) absorbed 10 amperes at 120 volts for 50 hours per week, equal to 56 units for 750 lamps. At 1d. per unit this equals 0·074d. per lamp per week. Wear and tear and renewals are taken at 1s. per lamp per annum, equal to 0·23d. per week. Interest on capital at 12 per cent. on the cost of the lamps at 7s. each is equal to 0·19d. per week. Owing to the time lost by workmen, which may be taken at, say, 15 per cent., the actual cost of oil will be reduced by that amount, or 0·049d. from 0·332d., leaving the net cost at 0·283d. per lamp per week.

Summarising these figures :—

Oil	0·283d.
Wick	0·003d.
Repairs	0·24d.
Batteries	0·074d.
Wear and tear	0·23d.
Interest on capital	0·19d.
Total (per lamp per week)	1·03d.

Thus the cost of oil illumination for miners' lamps works out to about 1d. per lamp per week.

If the cost of oil lamps at Murton Colliery approximates the same figure, it would appear from the statement already quoted, to the effect that the increased cost of electrical illumination is about 3s. per lamp per annum, that it is practically possible to instal and use electric hand lamps in substitution for ordinary safety lamps at a cost of about 1½d. per lamp per week. It will, of course, be recognised that such a cost is only possible in the case of a large and skilfully managed installation.

It should be observed that the cost per electric lamp at Murton (3·79d.) already given, referred to a period three or four years earlier than that to which the increased cost per annum over oil refers.

The interest on capital is not, however, included in these estimates and it is clearly not an item that can be left out of consideration. Fifteen hundred to two thousand lamps is a very ordinary supply for a colliery to stock, and consequently the initial outlay and heavy depreciation charges will make substantial additions to the cost of operation.

Advance in the use of electric hand lamps in mines has been

Digitized by Google

and continues to be retarded owing to the failure of the makers to produce a design which adequately satisfies mining conditions and which can be supplied at a cost of, say, 7s. to 10s. It is not essential that an electric lamp should be designed to imitate a gauze lamp, nor is it necessary that a lamp for general mining use should give an illumination of several candle power. It is quite possible to make and sell a pea lamp giving, say, 0·75 to 1 c.p. for 10 hours for less than 10s. and it is such a lamp that the mining industry requires. It should be noted that there must be no diminution of candle power within the working period. This is where every lamp known to the writer fails after a very short life. If soundly constructed, and the usual troubles—leakage, corrosion of conducting parts, badly made contacts, and inability to withstand rough usage and a certain amount of neglect—were effectively surmounted, there would come a "boom" in electric hand lamps which would eventually settle down into a large and steady annual demand.

It has frequently been objected that the electric hand lamp can never come into general use because it contains no means of indicating the presence of fire-damp. Numerous inventors have consequently sought, by providing spiral wires coated with salts of platinum and in other similar ways, to meet this supposed essential condition.

To attempt to find a satisfactory fire-damp indicator is, however, merely to delay the general introduction of electric hand lamps, and there is not the least necessity for such an addition to a miner's lamp. There is no reason why one gauze lamp should not be handed out with each batch of electric lamps, and hung in the working place where it can be easily seen, and where any outburst of "gas" would be most likely to occur.

This should satisfy those who think it is the proper thing to do; but it is perhaps worth while to observe that in a mine wholly worked by electric lamps the "safety" lamps which were retained to indicate the presence of fire damp would themselves be almost the only remaining source of explosive risk.

The extended use of electric hand lamps underground has been too long delayed. The dying cry of Goethe for "more light!" is felt in a very literal sense underground, where for 40 years men have laboured under practically the same lighting conditions, going to and fro and performing their daily tasks aided only by the dismal caricature of a flame derived from the thing called a safety lamp.

No other radical change in mining practice which is immediately discernible is so laden with promise—promise which will appeal alike to owners and to work people—as that of superseding the safety lamp for purposes of illumination.

No other change is so greatly desirable, and it is to be hoped that its consummation will not be long delayed.

Collieries and Power Supply.

THE PROFITABLE USE OF WASTE HEAT.

Summary.—The principal sources of waste heat are referred to and the most profitable method of utilising waste heat described. While the waste heat can be utilised in an independent installation the fact that the load factor of the power demand and the waste heat output do not coincide makes profitable use of the waste heat impossible without the co-operation of some independent user of the waste heat. Some of the chief waste heat stations in the North of England are described, and the success of the movement generally is indicated.

The great advantages which electric power offers in connection with almost all the operations performed in and about a pit are now generally recognised. This is shown not only by the various descriptions of installations contained in other parts of this issue, but also by the returns of the large electric power companies. On the North-East Coast alone some 40,000 H.P. is now being supplied from the power system of the Newcastle and allied companies for collieries alone. Remarkable, however, as are these figures and startling as has been the growth, there are still a very large number of pits which continue to utilise more or less antiquated machinery. In part this is due to the natural objection of the coal owners to scrap costly machinery which is not yet worn out (although it may be less efficient than electric power), and in part to conservatism.

And even where electric power has been adopted it is not always obtained in the cheapest possible way. Isolated and self-contained as a colliery usually is, it is only natural that the instinctive tendency is for it to produce its own electric power in the same way as it supplies many of its other requirements. As a matter of fact practical working experience has shown that in the exploitation of the waste energy resources of collieries, and the production of power therefrom co-operation with a large electric power company is most desirable, and in fact is the only way in which the owner of the waste heat can make the most profitable use of it.

There are four main sources of waste energy in the North of England, namely:—

1. Waste heat and surplus gas from coke ovens.
2. Exhaust steam from blast furnaces, blowing engines, &c.
3. Surplus gas from blast furnaces, and,
4. The less important and more miscellaneous cases of exhaust steam from winding engines, air compressing plant, fan engines and other plant.

At the present time comparatively little use has been made in this country of the waste gases from blast furnaces, although both in America and in Germany some considerable installations are now on trial; but in the other two directions a number of very interesting installations have been established, more especially in the Durham coalfields and on the Tees where it is the usual practice for the waste heat owners to co-operate with the Waste Heat Company. The latter is an intermediary between the coal owner or iron master and the power company, and the power station for the utilisation of waste heat is usually and most advantageously the joint property of the two parties first mentioned.

When it is a question of making use of waste heat there are four definite advantages obtainable, and only obtainable from a co-operative scheme. These are:—Firstly, the sale of all waste heat; secondly, a standby supply of power in case of breakdown, or of variation of output or shut-down during holidays and strikes; thirdly, technical assistance of the power company; and fourthly, the saving of capital expenditure.

As regards the first it must be remembered that the output of the waste heat is usually a very variable quantity. In coke oven practice the output although it may be fairly steady during the 24 hours, or during the week, may have other variations due to the variations in the output of coke due to the state of the iron trade or to labour troubles at the colliery. In connection with winding engines there are, of course, times when these are not running and when nevertheless electric power is needed for pumping, ventilating and other purposes. Unless there be some outside source of power available, the putting down of an independent installation of boiler plant, &c., is necessary. At first sight it often appears as if this is more economical than purchasing from an outside supply. Makers of machinery and others are naturally anxious that coal owners

Digitized by Google

should put down their own installations; but the fact is often overlooked that the actual cost of the machinery often represents only about half the total outlay necessary to obtain a complete and reliable installation. If the matter be gone into as carefully as a chartered accountant would do, it will usually be found that the interest and depreciation charges upon the total capital expended is such as to make the cost of the power of an independent plant, with sufficient spares to insure reliability, 20 per cent. to 50 per cent. more than the cost of an electric supply depending upon the conditions.

So much for the cost. Co-operation, however, has the additional advantage that it enables a waste heat owner to dispose of the whole of his waste heat. It rarely happens that the waste heat owner is able to dispose of the whole of his waste heat in his own works or to find anyone in his vicinity, except a power company, whose load

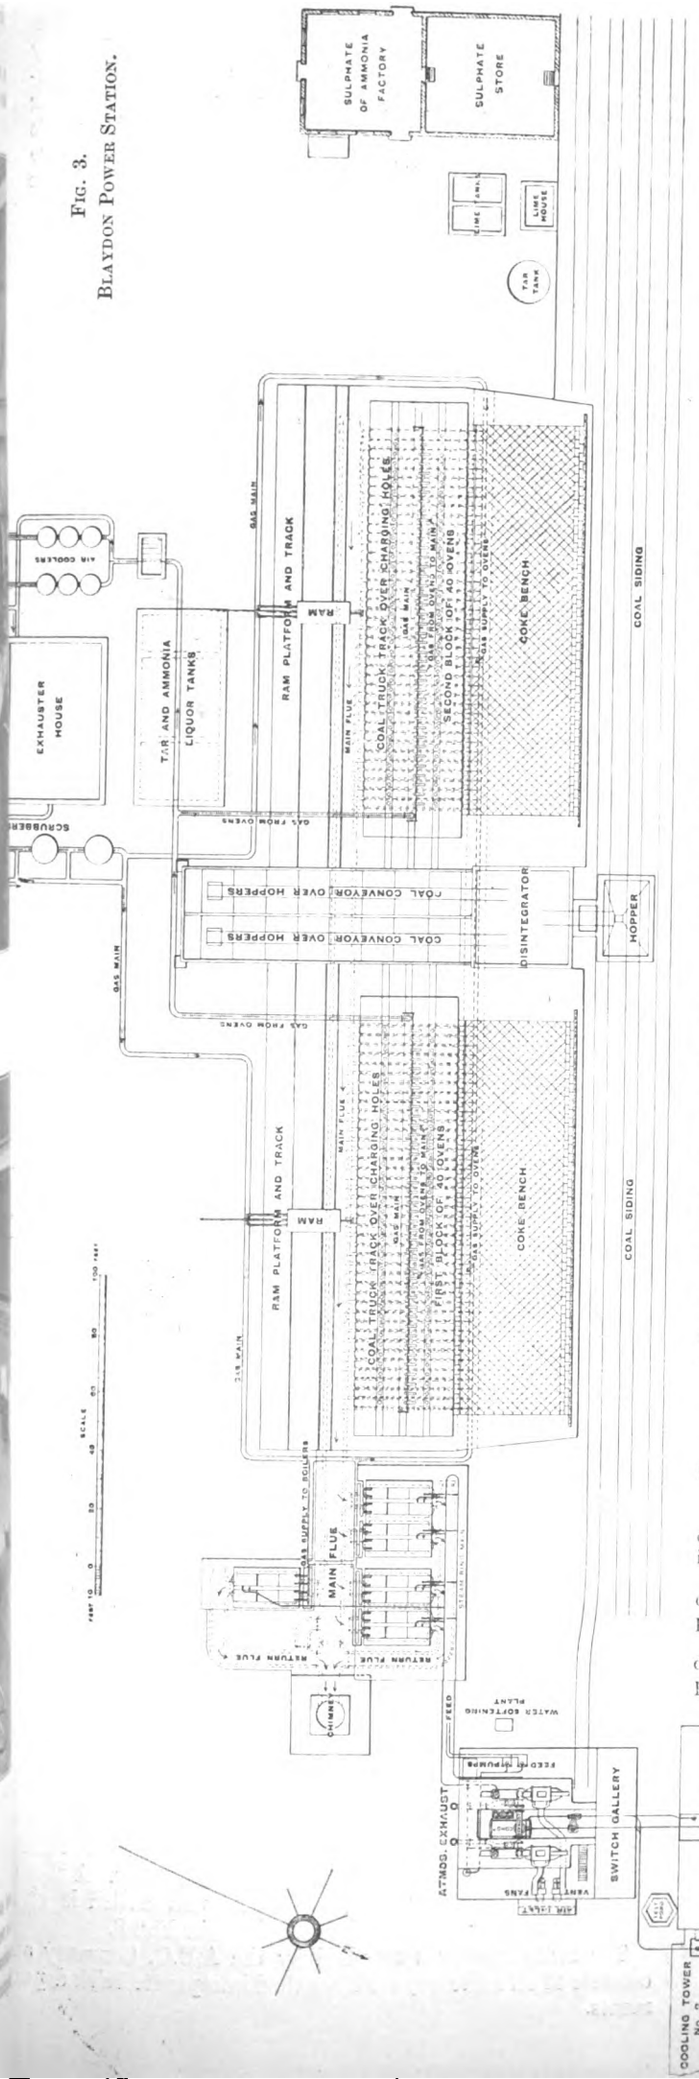

Fig. 3.
Blaydon Power Station.

coincides exactly with his own output of waste heat. Thus, however efficient and perfect a plant may be put down, a considerable proportion of the waste heat produced during the 12 months remains waste heat if the plant be an isolated one. A large power company, however, with a network extending over hundreds of square miles, has such a variety of demands on its system that it is able to make use of all the waste energy it can obtain day or night, week-ends, Sundays and holidays. If the proportion of its power derived from waste heat increases, it merely burns less coal at its coal fired generating station and *vice versa*. In other words it can use every bit of waste heat it can buy. This, the fact that he sells the whole of his waste heat, is therefore another factor that has to be considered by the waste heat owner in comparing an independent installation with the co-operative scheme. Thirdly, the advantages of a stand-by supply and technical assistance in cases of trouble are all, of course, ones that are obvious enough to electrical engineers, and becoming more and more appreciated by colliery managers. The fact that the supply of power to the mine is totally unaffected by the operation of the colliery machinery or the coke ovens is one that obviously conduces to efficient working.

In view of these various considerations it is not surprising that the majority of the owners of waste heat upon the North-East Coast have gone in for co-operative schemes. Waste heat stations have been erected at Blaydon by the Priestman Power Company in connection with the Priestman Collieries, where coke oven gas is used, at Spennymoor in connection with the Tudhoe Ironworks of the Weardale Iron & Coal Co., at Newport in connection with the blowing engines and blast furnaces of Sir B. Samuelson & Company, at Teesbridge in connection with the blowing engines of the Teesbridge Iron Works, at Bankfoot, in connection with the coke ovens of Messrs. Pease & Partners, while additional installations are in hand at Bowden Close, Port Clarence, Aryesome, Lackenby, Stobton and Hordern.

The Blaydon Station (Figs. 1 and 3).

The principal plant at the Blaydon Station, the earliest to be put down, consists of :—

Boilers.—Five Babcock land-type boilers of 4,780 sq. ft. fired by gas and waste heat.

Feed Pumps.—Two Weir's steam-driven feed pumps each of a continuous capacity of 50,000 lbs. per hour.

Turbo-alternators.—Two Parsons 1,400 kw. Turbo-alternators running at 2,400 revs. per min., and generating at 5,750 volts.

Condensers.—One Mirrlees-Watson surface condenser of 4,300 sq. ft., and one Cole, Marchant & Morley surface condenser of 2,500 sq. ft. each fitted with motor-driven Edwards three-throw air pumps.

Cooling Towers.—Two enclosed type, built respectively by Richardson-Westgarth and the Midland Engineering Company.

Switchgear.—A 5,750-volt board by Brown, Boveri, and 440-volt board by Reyrolle & Co.

Transformers.—A 1,300 kw. British Electrical Transformer Co.'s three-phase oil cooled transformer supplying at 440 volts to the colliery and several smaller transformers to supply the station auxiliaries, &c.

Spennymoor Station.

The principal plant at the Spennymoor Station consists of :—

Boilers.—Four Richardson-Westgarth "Nesdrum" boilers of 5,320 sq. ft. fired by gas.

Economiser.—Green's type, 640 tubes.

Feed Pumps.—Two Clarke, Chapman steam-driven feed pumps of a continuous capacity, together of 150,000 lbs. per hour; steam exhausting into hot well.

Turbo-alternators.—Four Richardson-Westgarth Parsons-type turbine coupled to 1,250 kw. Westinghouse Alternators, running at 2,400 revs. per min., and generating at 2,875 volts.

Condensers.—Two Richardson-Westgarth "Contraflo" surface condensers of 4,400 sq. ft. each with motor-driven Edwards three-throw air pumps, and motor-driven centrifugal circulating pump.

Cooling Towers.—Two Richardson-Westgarth enclosed type.

Motor Generators.—Two 150 kw. for supplying direct current for lighting.

Switchgear.—A 2,875-volt board by the A.E.G. Company; also a 440 alternating-current enclosed type, and 500 volt direct-current board by Reyrolle & Co.

Sub-station.—This contains five step-up oil-cooled transformers from 2,875—20,000 volts. Two of the transformers are by the A.E.G. Co. The three others are by the Westinghouse Co. All surplus current over and above the requirements of the colliery &c., is transformed as above to 20,000 volts, and delivered into the cable networks.

THE NEWPORT STATION.

The principal plant at the Newport Station (Figs. 2 and 6) is as follows :—

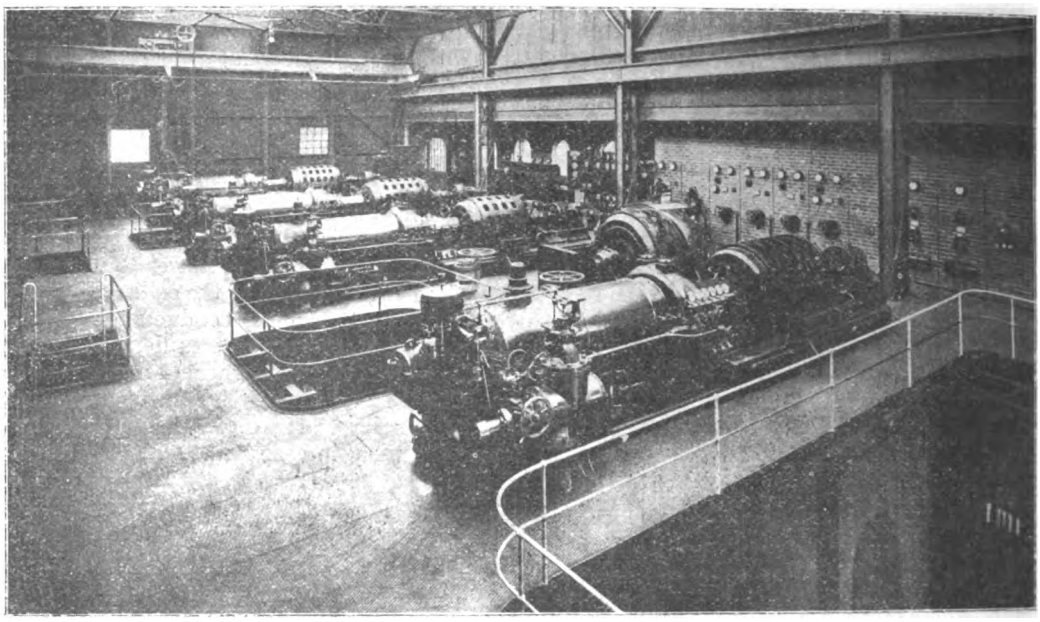
The capacity of this station is 5,500 kw. The main equipment consists of four 1,250 kw. turbo alternators which are driven by exhaust steam from two main sets of blowing engines situated in Messrs. Samuelson's Works some 200 and 1,000 ft. away from the turbines respectively.

The turbines are of Messrs. Parson's type, two sets being of Messrs. Willans & Robinson's manufacture and remaining two sets of the British Westinghouse Company's manufacture. The steam after exhausting from the blowing engines and before reaching the turbines is superheated by independent superheaters fired by blast furnace gas and designed to impart about 150 degs. superheat to the steam. A 500 kw. high-pressure Brush Company's turbo-alternator is also installed in the power station. This machine is driven by high-pressure steam surplussed over from Messrs. Samuelson's high-pressure steam range. This turbine is arranged to exhaust into the low pressure steam main supplying the exhaust turbines. Each low pressure turbine exhausts into its own surface condenser supplied by the turbine manufacturers.

The condensers for the turbine supplied by Messrs. Willans & Robinson are provided with Messrs. Parson's Augmentor Condensers and Edwards air pumps. The condensers for the turbines supplied by the Westinghouse Company are provided with Leblanc rotary air pumps and rotary water extraction pumps. The circulating water for the condensers is obtained from the River Tees, a pump house being built on the River side quay where three pumps each capable of dealing with 636,000 gallons per hour are installed. Two of these are continually in service, the third pump being available as spare to the other two. The pumps are of Messrs. Worthington's manufacture, and are of the submerged type. They are connected to the motors in the pump house overhead by means of vertical shafts. The motors are of the three-phase type, and of the British Thomson-Houston's Company manufacture. With the barometer at 30 in., each of the condensing plants is capable of maintaining under normal conditions a vacuum of 29½ in.

All four main alternators are built by the British Westinghouse Company, and are designed to run at 2,400 revs. per min., and generate electrical energy at 2,875 volts 40 cycles per second. The 500 kw. alternator was manufactured by the Brush Company. The large alternators are duplicates of those at the Weardale Station (Fig. 4). This size is chosen because it is the largest machine that can be built to a speed of 2,400 revs. per min. a relatively high speed favourable to turbine economy. A plan of this station is given in Fig. 8.

The switchgear was supplied by the A.E.G. Company, consists of oil switches, each installed in separate brick compartments.



By permission of "The Iron and Coal Trades Review."

FIG. 4.—WEARDALE WASTE HEAT STATION. CAPACITY, 7,330 H.P.

Three feeders fitted with Merz-Price protective gear and each consisting of three 1 sq. in. three-phase cables in parallel, carry the current from the power station to the Cleveland and Durham Power Company's sub-station situated at the west end of the works. From this point some of the current is used directly in the local 2,750-volt network, but the greater proportion is transformed up to 11,000 volts by five 1,000 kw. oil-cooled Westinghouse transformers, and fed into the Power Company's network of high tension mains.

The station is the property of the Waste Heat and Gas Electrical Generating Stations Ltd.

The Bankfoot and Teesbridge Stations.

The principal plant at the Bankfoot Station consists of:—Five land type Babcock boilers, two 1,200 kw. Richardson-Westgarth-Parsons type turbines, and Westinghouse alternators and Reyrolle ironclad switchgear, but large extensions are contemplated.

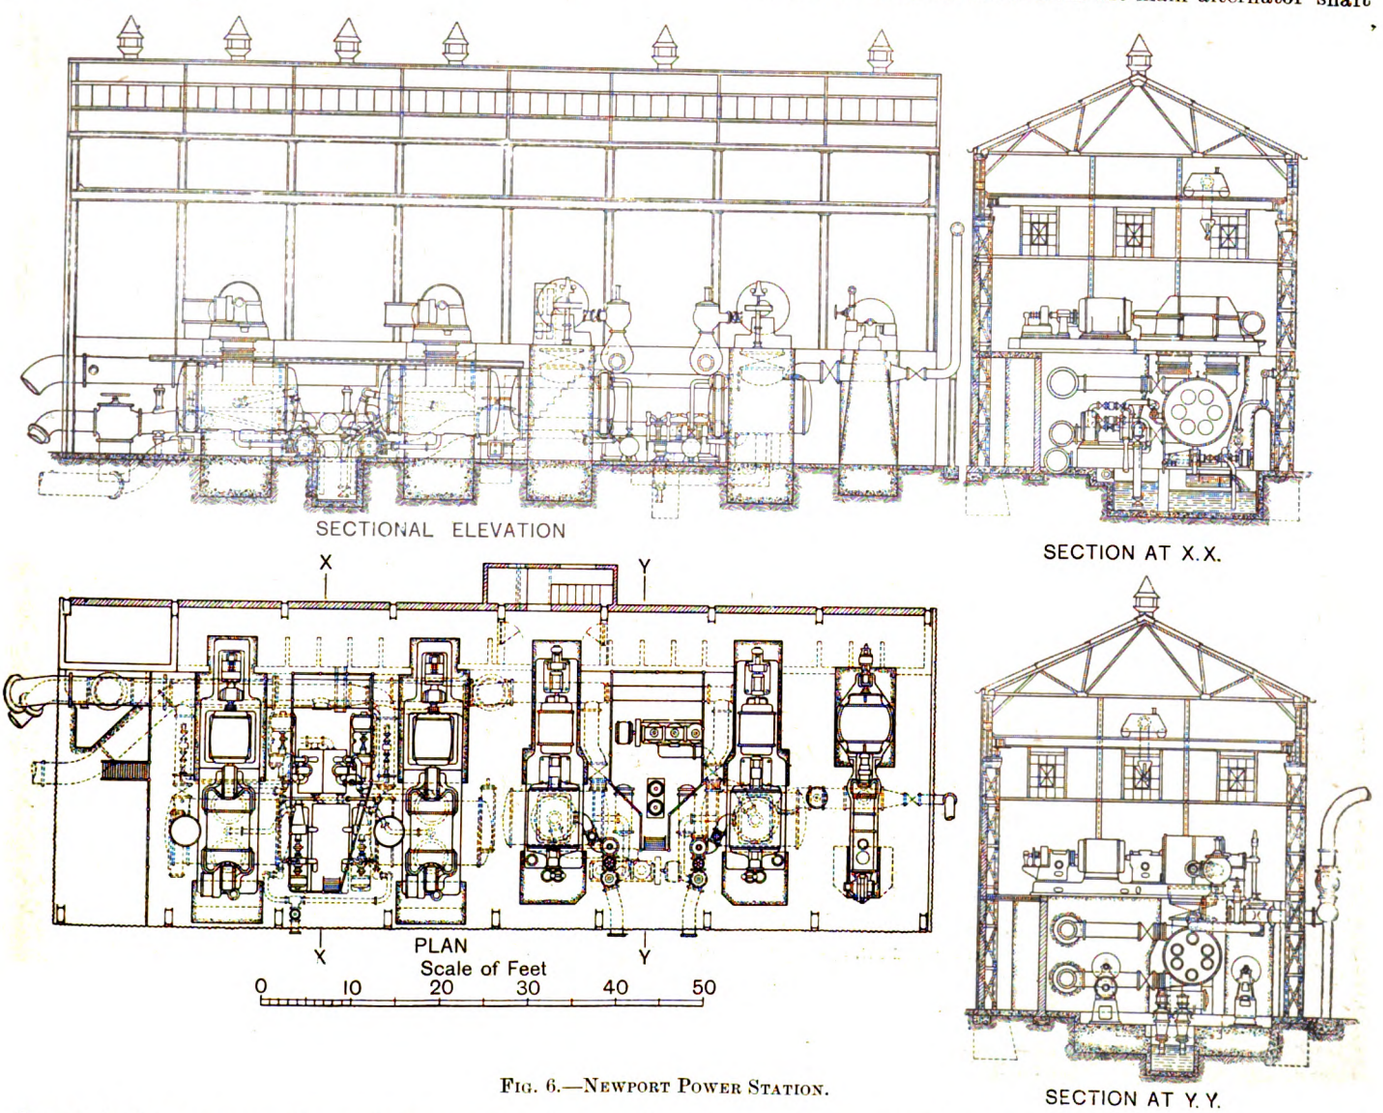

FIG. 6.—NEWPORT POWER STATION.

One of the latest among the waste heat stations is a small exhaust steam plant, using the steam from the blowing engines at the Teesbridge Iron Company's Works.

The plant installed consists of one horizontal "Curtis" turbine manufactured by the British Thomson-Houston Company, and coupled direct to a British Thomson-Houston Company's three-phase alternator. The normal output of the turbine is 1,250 kw. at 2,750 volts and 40 cycles when running at a speed of 2,400 revs. per min., and when supplied with dry saturated steam supplied to the stop valve, at atmospheric pressure.

The condensing plant (Fig. 5) is of the surface type manufactured by Messrs. Mirrlees-Watson & Company, and is provided with three-throw Edwards air pumps. The capacity of the plant is such as to enable 91·66 per cent. perfect vacuum being maintained when dealing with the full amount of steam required to run the turbine on normal load, and when supplied with 5,500 gallons of circulating water at a temperature of 80°F.

The circulating water pump is of Worthington's manufacture, driven direct by a British Thomson-Houston three-phase motor, and draws water from the cooling ponds situated about 100 yds. away from the station. The cooling pond occupies about one-third of an acre, and is provided with spraying nozzles of Messrs. Gjers & Harrison's patent type. The connection between the cooling pond and the station is made by means of 18 in. pipes.

For the make-up water supply to the cooling pond a separate 6 in. pipe service has been run to the river Tees, where a small 5 in. centrifugal pump is fixed which draws water from the river at low tides, the reason for pumping at low tides being that the water is generally fresh at such times.

The exciter is driven direct from the main alternator shaft the current generated by the exciter being at a pressure of 70 volts.

The exhaust steam from the turbine is taken from three blowing engines which previously exhausted into the atmosphere. The steam is collected from these engines by an 11 in. and 20 in. exhaust main provided with atmospheric valves which open up to the atmosphere in the event of the exhaust steam pressure rising above a predetermined value. The steam after being collected in this exhaust main is passed through an oil separator and from thence direct to the turbine; the working pressure at the turbine stop valve being as near as possible equal to the atmosphere.

Contrary to usual practice, all synchronising and switch gear is fixed in the main sub-station situated some 200 yds.

away from the power station, there being only a meter panel in the power station. The regulation of the machine for synchronising is effected by means of a small electric motor attached to the governor spring. This motor is operated by the switchboard attendant who is synchronising in the distant sub-station referred to. At the sub-station the current generated is stepped up to the system pressure of 11,000 volts by means of static transformers.

The plant at the other stations is, as a rule, of the same general type.

Advantages of Utilising Waste Heat.

The objects for which the Waste Heat Company exists may be summarised as follows :—

(*a*) To erect waste heat generating plant.
(*b*) To acquire the waste heat from owners.
(*c*) To sell the surplus output to the Power Company.

1. The principal advantage to the Waste Heat owner of an arrangement with them is that he is saved capital outlay; this is due partly to the fact that he in general finds only half the capital for the plant, and partly to the fact that the cost of the plant is low, since no standby units are necessary.

2. The second advantage to the Waste Heat owner is that for his own power requirements he gets first call upon a com-

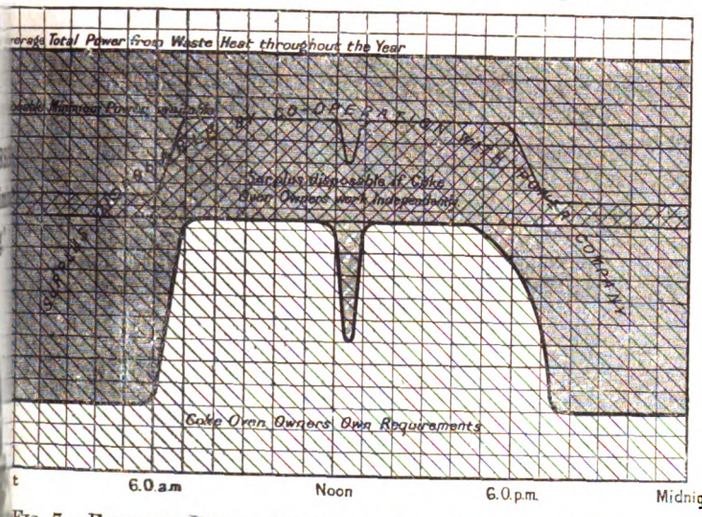

Fig. 7.—Estimated Daily Output and Load Curve of Waste-Heat Station at Crook.

Electricity utilised by coke-oven owners at mines and ovens = 5½ million Board of Trade units per annum. Maximum surplus available for outside sale, if coke-oven owners work independently = 2½ million Board of Trade units per annum. Surplus disposable by co-operating with power company = 10 million Board of Trade units per annum.

paratively large and well-arranged power plant, which is not only a very reliable one in that it works under the most favourable conditions for any power plant, namely day and night at full load, but is, in addition, connected to the cable system of the electric power companies so that standby current is instantly available in the event of any accident to the local plant.

3. The third advantage to the Waste Heat owner of a joint arrangement is that all surplus output not required by him is delivered into the electric power companies' system of mains, and it is this source of revenue which makes the outlay in these generating plants so profitable to owners of waste heat.

4. The power requirements at no colliery, nor even at any group of collieries, represent anything like a constant load. The pumping and ventilating is steady, but the other often larger demands are subject to momentary variations and extend to most over 16 hours a day. In the case of blast furnaces the requirements are in some cases 24 hour ones, but the momentary variations in load are considerable.

5. The output from waste heat plant, though steady over 24 hours, is subject to considerable variations due :—

(*a*) To repairs to the coke ovens or blast furnaces.
(*b*) To variations in state of trade.
(*c*) To climatic conditions.

6. Nothing but a diagram can properly bring out the want of coincidence between the power requirements and the power output either of a colliery or ironworks; such a diagram as Fig. 7 shows at a glance the enormous advantage of connecting up the local waste heat and generating plant to the power company's system of mains into which the surplus

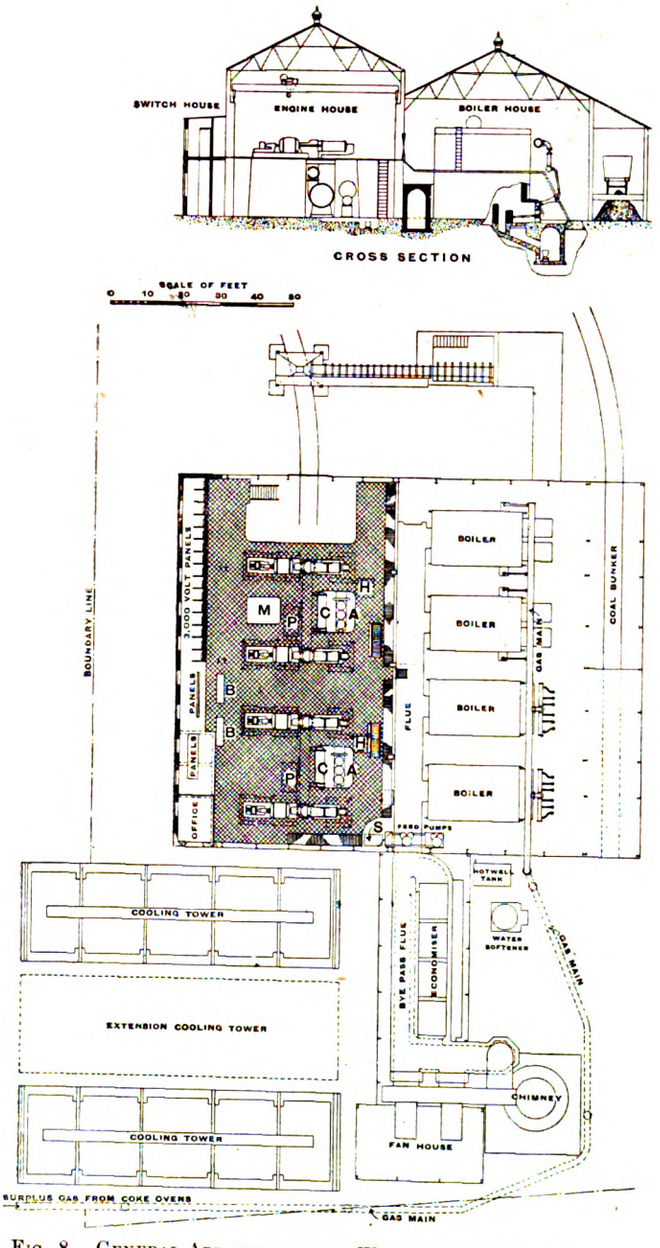

Fig. 8.—General Arrangement of Weardale Waste Heat Station.

can be generated, and from which a deficiency of power is easily made up instantaneously.

It is interesting to note from the third and latest report issued by the company—the Waste Heat and Gas Electrical Stations, Ltd.—that it is rapidly increasing its profits and extending its operations. Dividends of 8s. are now being earned while the whole of the cost of stations is written off during the term of the agreements—a very sound policy. No new stations are erected unless and until long term agreements have been entered into with the owner of the waste heat on the one hand and the power company on the other, by which the latter purchases all the power produced. The waste heat company thus bears none of the cost of distribution or obtaining consumers and fills the profitable role of an intermediary.

Recent Electric Power Developments in North Staffordshire Collieries.

In general, the North Staffordshire coalfield is badly handicapped as regards competition in the open market on account of its difficult underground conditions. It has been necessary, therefore, in order to enable owners of collieries situated in this area to compete satisfactorily with those in other parts of the country, for them to adopt the most up-to-date means of working, and thus to reduce their costs of production to as low a figure as possible. A short description of one or two recent equipments in this area will, therefore, we feel sure, be of great interest to colliery engineers and electrical engineers who specialise in colliery equipment. Through the courtesy of Messrs. Robert Heath & Sons and the Birchenwood Colliery Co., and particularly their agent, Mr. Jas. R. L. Allott, under whose personal supervision the whole of the work has been carried out, we are able to give a short description of the equipments at their pits as far as they are at present in operation.

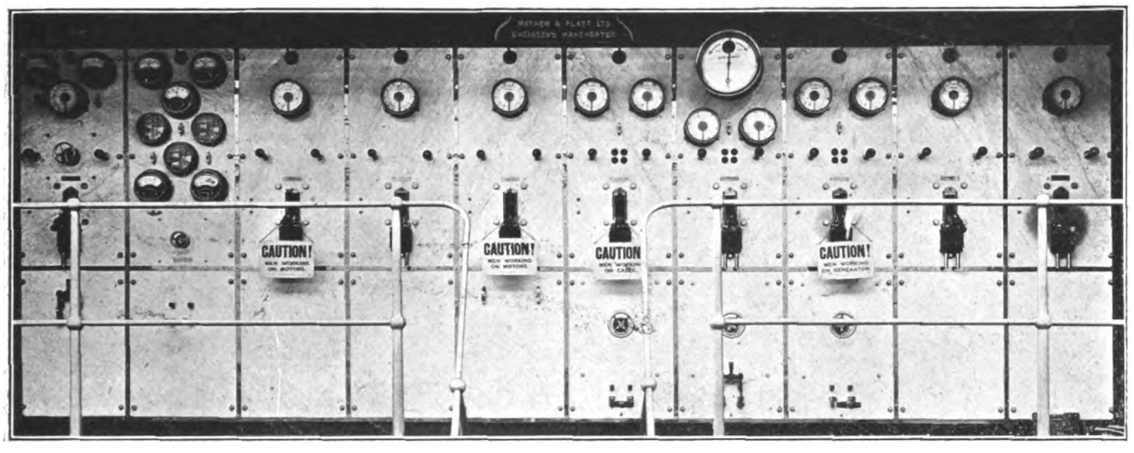

FIG. 1.—FRONT VIEW OF SWITCHBOARD.

The Birchenwood Colliery prior to 1908 was entirely steam driven, there only being a small electrical plant for surface and pit bottom lighting. Power was obtained from several ranges of boilers, fired in some cases by waste gas from bee-hive coke ovens and in the others with slack. This colliery labours under the double disadvantage of having a large amount of water to

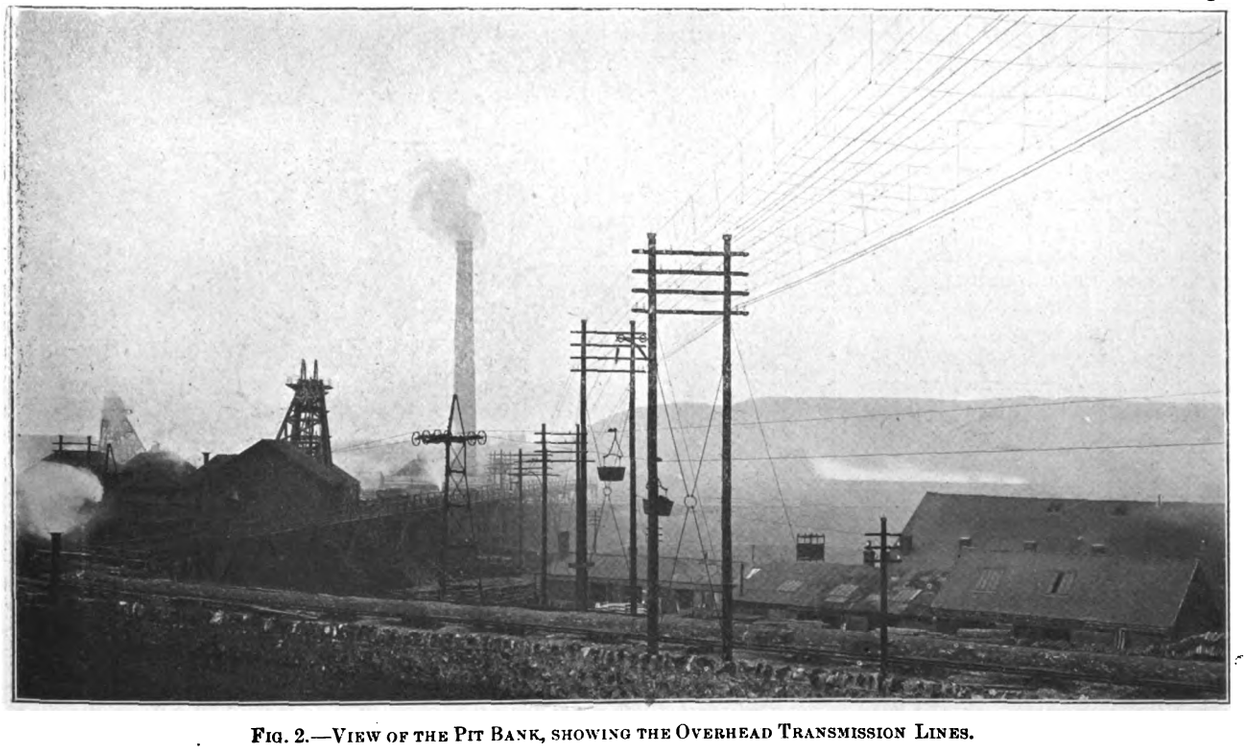

FIG. 2.—VIEW OF THE PIT BANK, SHOWING THE OVERHEAD TRANSMISSION LINES.

Digitized by Google

deal with, and steep inclinations in the workings, necessitating a considerable amount of power to bring the coal to the shaft bottom. The pumping was mainly done with spear-rod shaft pumps, steam driven, and compressed air pumps inbye.

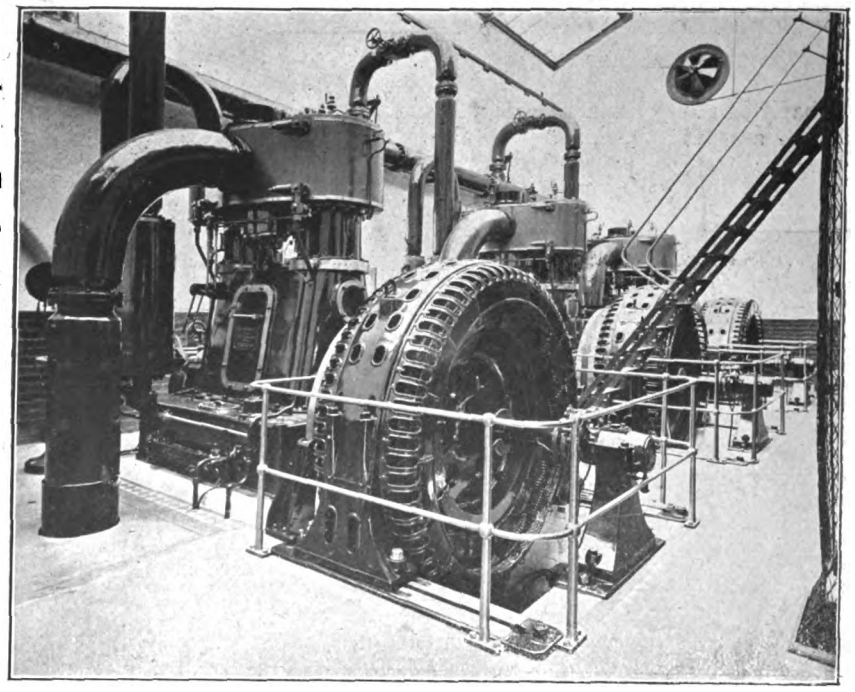

FIG. 3.—POWER HOUSE AT BIRCHENWOOD COLLIERY.

As now remodelled, the steam still supplies the source of power, but instead of several isolated units of boilers the outlying plants have been shut down, and the power is transmitted electrically to motor-driven turbine pumps. Owing to the nature of the mine, compressed air is still retained for the in-bye power, but, on the other hand, the electric drive has been made use of for the main road haulages in the principal pit. In addition, on the surface, all the extensions which have been recently made are electrically driven, and various small isolated engines have thus been replaced by electric motors.

This, in general, is an outline description of the Birchenwood present equipment. The plant has been running for a period of about 1½ years, and has given very good working results. Turning now to a more detailed description, the power house is built at the gable end of the air compressor building. In it are installed three Belliss & Morcom–Mather & Platt combined sets, each having a capacity of 430 B.H.P. when running at a speed of 375 revs. per min. The engines work at 90 lb. steam pressure, and are arranged to run either condensing through ejector condensers, or non-condensing. Steam is taken off the main range supplying the winding engines. The three-phase alternators supply current at 2,600 volts and a frequency of 50. Fig. 3 gives a very good idea of the lay-out of the power house. The condensers are supplied with cooling water from a pond under static head, the water being returned after going through the condensers by two Mather & Platt low-lift turbine pumps each having a capacity of 1,500 to 2,000 gallons per minute with a 70 ft. head.

The switchboard, to suit the lay-out of the building, has been raised on a gallery down one side of the engine room. Figs. 1 and 4 show respectively the front and back of this board. It is a good example of a high-tension slab board, and comprises circuits for the three main alternators, two circulating pumps, one motor-generator, one steam exciter, one rotary convertor and two main feeders for the pits.

The rotary convertor, which has been supplied by the British Westinghouse Co., is of 75 kw. capacity, and has been installed to enable the steam lighting plant to be shut down and the existing continuous current lighting supplied from the new three-phase plant.

A particular point to which attention may be called in connection with this equipment is the way in which the power has been carried from the power house to the points where it is required. The engineers responsible for this work have kept the obvious fact well to the foreground that one weak link in the chain of the complete equipment would lower the efficiency of the whole plant to a considerable degree. The transmission of the power, therefore, both overhead and underground, has been carried out on the best possible lines. Fig. 2 is a typical view of the colliery bank, showing clearly the arrangement whereby the high-tension supply is transmitted overhead. As the supply for the colliery had to cross not only many railway sidings, a ropeway and an overhead bridge, as well as public rights of way, it was particularly essential that satisfactory guard netting should be adopted. The whole distance of the overhead transmission (about ½-mile) has, therefore, been guard netted in a thorough manner, as will be seen from Fig. 2.

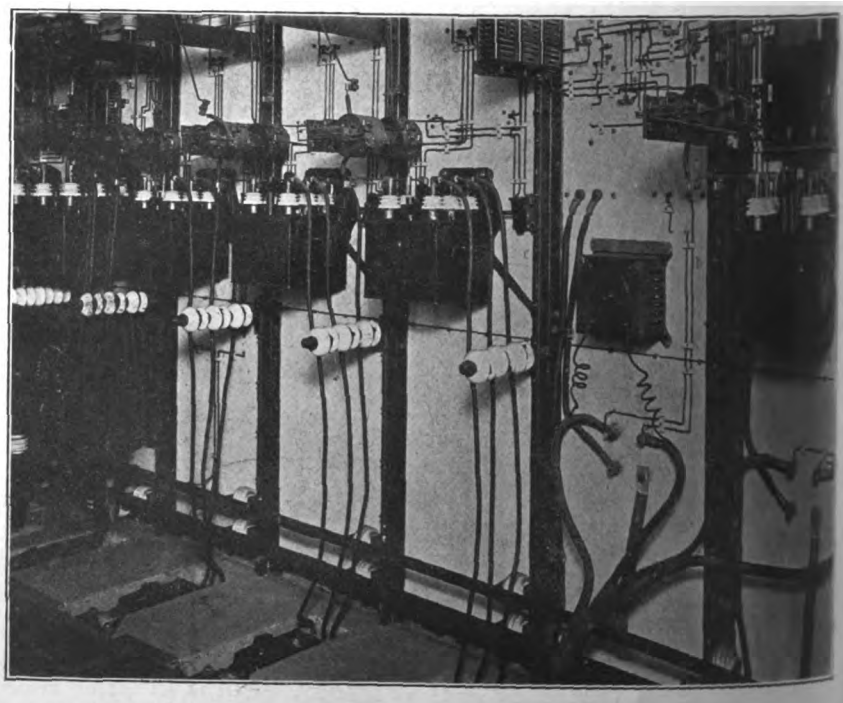

FIG. 4.—BACK VIEW OF SWITCHBOARD.

Digitized by Google

The transmission line is supported on H poles, which vary from 40 ft. to 60 ft. in height, and below the guard net low-tension lighting wires are run.

Two overhead circuits run from the power house. The first supplies the shaft cable for No. 18 pit. This shaft, which is 430 yds. deep, is supplied by a 19/16 three-core solid bitumen double-wire armoured and served cable. The cable is supported about every 30 yds. on long oak clamps with swing suspension. Half way down the shaft is a pump house, in which is installed a Mather & Platt single-chamber high-lift

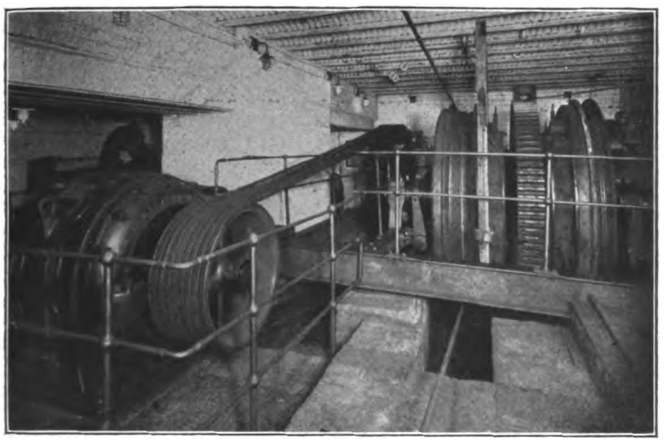

FIG. 5.—MOTOR-DRIVEN ENDLESS ROPE HAULAGE.

pump having a capacity of 500 gallons per minute with a 120 ft. head. This pump is driven by a high-tension 27 H.P. motor. The pump house is of the massive construction characteristic of the whole of this installation for the underground machine houses. The Birchenwood Colliery Co. held the view that if a machine was installed in the first instance in good surroundings then it was an incentive to the attendant and all concerned to keep it in perfect order. The actual results are certainly bearing this view out.

At the shaft bottom the cable goes inbye a short distance

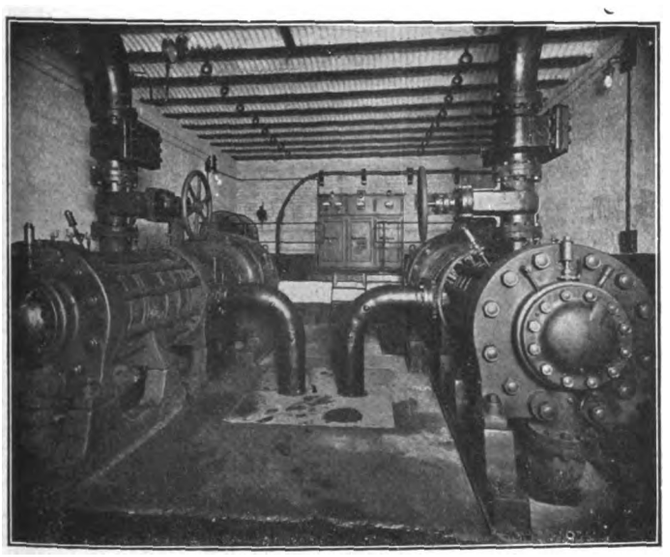

FIG. 6.—PUMP HOUSE AT BIRCHENWOOD COLLIERIES.

into a large machine room containing a haulage engine and another turbine pump. Fig. 5 illustrates the endless rope haulage with its motor, the pump being behind the motor. This haulage is of the two-rope endless type running at 2 miles per hour. One rope works the main road, the other winds up a steep dip from the lower workings. The pump is a Mather & Platt five-chamber turbine pump having a capacity of 500 gallons per minute at a total head of 570 ft. It is driven by a high-tension 130 H.P. motor.

The other overhead circuit goes right across the colliery yard to No. 14 shaft. Here it divides up into four feeders, which supply (1) a 90 H.P. motor driving a draining band in the washery plant, (2) a 100 k.v.a. transformer stepping down to 500 volts for the motors on the surface in this vicinity. These motors comprise one 30 H.P. on the aerial ropeway, two 35 H.P. on the coke-oven charging rams, two 10 H.P. on the same work, one 9 H.P. driving the small screening plant, and one 6 H.P. driving the grease-making plant. The transmission to these

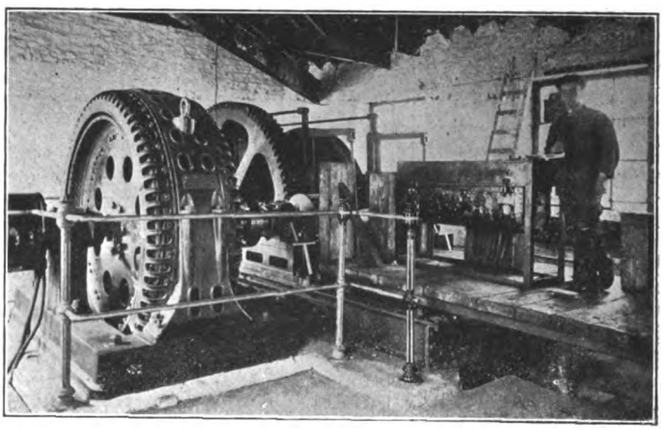

FIG. 7.—WINDING ENGINE AT OAKWOOD DIP.

motors is, in general, overhead; but in one or two cases it consists of a three-core unarmoured cable slung by suspender wire. (3) This feeder goes across country to the Nelson Pit, a distance of about a mile, where it supplies a pumping plant. This circuit is run overhead, bare wire being used except where the roads are crossed. The pump is a Mather & Platt combination, of a capacity of 500 gallons per minute to a head of about 250 ft. This plant lifts surface water up to the colliery for boiler feed purposes. The fourth and main supply from the No. 4 bank is the feeder down No. 4 shaft. This is essentially a pumping shaft, the power being entirely used for this purpose. The shaft cable is of 1,000 H.P. capacity. Part of

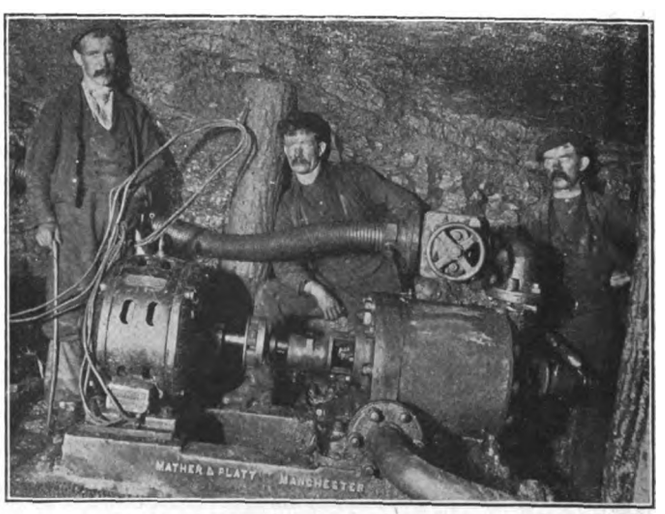

FIG. 8.—AN EARLY MATHER & PLATT MULTI-CHAMBER PUMP.

the way down the shaft it is taken inbye to feed a pump lifting water brought over from the old ironstone pits. This water is very corrosive, and the pump to lift it has, therefore, been made entirely of gunmetal. For this part of the installation the pump house has been built about 20 yds. from the shaft. The pump is of 500 gallons capacity, the motor being 130 H.P. At the shaft bottom is a large pump house, which is illustrated

Digitized by Google

in Fig. 6. The two pumps in it are each capable of delivering 900 gallons per minute to a total head of 900 ft., being driven by 375 H.P. motors. The pump house is a very large, well-constructed room, as will be seen from Fig. 6.

Besides this plant there are also large extensions in hand at this colliery, of which we shall hope to publish a description in due course. We may say, however, that the engineers responsible for this scheme are erecting at the present time three two-cycle gas engines driving alternators direct coupled, the capacity of each set being 500 H.P. These will be worked from a large gas power plant which is now being installed. The gas will be made mainly from refuse. Further, about 100 motors, of capacity varying from 4 H.P. to 750 H.P., including two huge pumping units, each having a capacity of 1,800 gallons per minute to a head of 950 ft., are being installed in a central pumping station which will deal with several pits. Power will be transmitted at extra high pressure from this colliery to other collieries belonging to the same company, where it will be led underground for pumping, hauling and coal cutting. The equipment at the Birchenwood Colliery will, therefore, in about two years' time, rank among the most extensive in the United Kingdom.

The shaft cable is 0·25 solid bitumen double wire armoured 3-core and is laid underground from the power house to the shaft. It is supported in the shaft in the standard manner adopted by the engineers. Adjacent to the shaft bottom is a pump room where the shaft cable terminates. Here a Mather & Platt patent turbine pump, with a capacity of 500 gallons per minute at a 725 ft. head, is driven by a 186 H.P. motor. The cable is also taken inbye to drive a 40 H.P. endless haulage, and goes down a dip to supply two turbine dip pumps mounted on trolleys, each pump being about 200 gallons in capacity.

In addition to the above plant the engineers have also in hand for the Norton Colliery a complete electrification scheme, the power for which will be obtained from two 600 H.P. two-cycle gas engines, the motors being employed for driving haulages, pumps and for ventilating purposes.

The whole of the above equipment has been carried out by Messrs. Mather & Platt, of Park Works and Salford Iron Works, Manchester, to the specification of Mr. J. R. L. Allott. We understand that Messrs. Mather & Platt have also very large orders in hand for collieries both at home and abroad, and for power equipments of various natures. At present they have

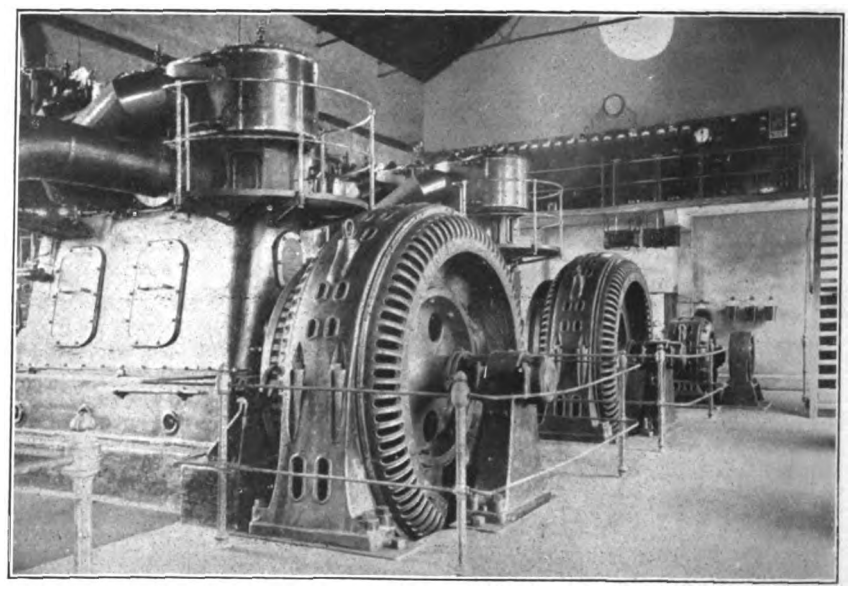

FIG. 9.—POWER HOUSE AT BRYN COLLIERY.

Although a much smaller, and therefore to many a less interesting, plant, is the complete equipment which has recently been started up at Messrs. Robert Heath & Sons, Grange Colliery, Burslem. The power house has been built adjacent to the existing Cornish pump, so that the same man can look after the three engines. In it are two Belliss & Morcom–Mather & Platt generator sets, each of a capacity of 250 H.P. when running at 428 revs. per min. The engines, which work at 90 lb. pressure, are arranged to run condensing or non-condensing at will. Condensing is effected by ejector condensers, the water used being that which is pumped out of the pit. To get the necessary head a cast-iron tank has been built on the top of the power house, and the whole of the pit water is lifted into this tank, whence it flows, after straining, to the condensers. On account of the small size of the colliery, 500 volts has been chosen for the supply pressure. Adjoining the engine house is a Walker Bros.' patent mine fan of about 50,000 cubic ft. capacity; this fan is driven direct by a 40 H.P. motor. The brick works are also driven electrically by a 90 H.P. motor. The whole of the pit bank and buildings have been lighted electrically through a step-down transformer. The calcining rucks are also lighted by 1,000 c.p. metal filament lamps, thus doing away with the large amount of coal used in the fire pots which had been used for illuminating purposes.

in their works about 40,000 H.P. of machinery in progress for colliery purposes only. In the South Wales district this firm have installed some very important equipments, and during the recent labour troubles, both at the pits of the Glamorgan Coal Co. and at the Coytrahen Park Colliery, the running of their pumps was essential in order that the owners might keep the mines dry during this trying period.

Fig. 9 illustrates the power house of Messrs. Baldwins, of Bryn Colliery, which contains two 650 H.P. Belliss & Morcom-Mather & Platt generators and sundry auxiliary machinery. The main switchboard is on a gallery, and is of a very extensive order, remote control, mechanically operated switchgear being used. At this colliery a considerable number of machines have been installed, among them being three single-rope haulages of massive size, which are provided with 250 H.P. motors capable of exerting as much as 750 H.P. on emergency. The robust construction of these machines is perfectly intelligible from Fig. 7, which illustrates a gear of this size used for winding up the Oakwood dip.

Fig. 8 is interesting in that it contains one of the earliest of Mather & Platt's multi-chamber pumps, which was installed many years ago in one of the South Wales collieries, and is still doing excellent service.

WHY THE EXCELLO?

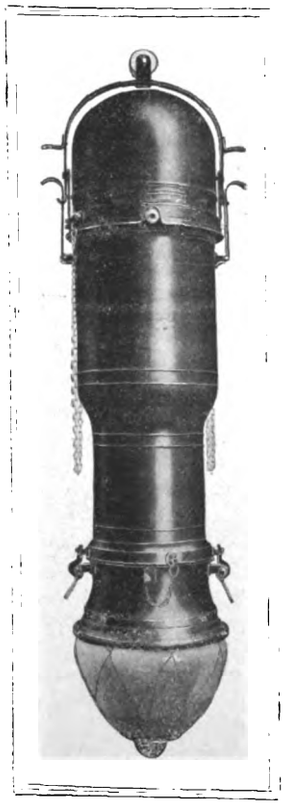
BECAUSE IT IS THE BEST LAMP for lighting large spaces—Colliery Yards, for instance.

The immense volume of light and the excellent distribution give just the right effect for efficiently lighting large areas.

This effect is further enhanced if the lamp is fitted with the DIOPTRIC GLOBE, which evens up the illumination of the area to a remarkable degree.

The Lamp illustrated here is one of the latest pattern Excellos, fitted with the DIOPTRIC GLOBE.

The EXCELLO FLAME ARC LAMP (with the Two Years' GUARANTEE).



Fullest information promptly sent on application.

The Transmission of Power.

The great increase in the electrification of colleries and mines, which are usually situated away from the routes of the electric supply mains, has directed considerable attention to the methods available for the transmission of power to the points of use. The subject has also come into prominence recently through the issue of the Home Office Committee's Report on the Use of Electricity in Mines, in which much attention is paid to the above subject.

In the shafts and workings insulated cables only may be used for transmitting energy. In a few instances rubber-insulated cables have been used, but they are very costly. More usually, paper or bitumen-insulated cables are employed. In the shafts, either type should be double wire armoured.

Inbye.—Wire-armoured cables also offer many advantages because of the ease with which the armour can be made electrically continuous and so an earthed circuit can be obtained to the surface for earthing motor frames and switchgear. In addition to affording considerable protection from mechanical damage, the armour assists materially in preventing "open sparking" and the risk of explosion (if gas is present) in the event of a leakage of current from a cable. The Home Office Committee also recommend the use of a lead sheath over the cable below the armour as a great protection against open sparking. With bitumen cables a copper tape below the armour may be employed for the same purpose and to give the required conductivity. In the case of paper-insulated cables, a lead sheath is to be preferred to a bitumen sheath although it is somewhat heavier. Objection has sometimes been taken to lead-covered cables in collieries because of the corrosive effects of some waters, but it should be quite clearly understood, it is pointed out, that leading English cable makers know how to protect the armour and lead against corrosion. In all usual sizes single wire-armoured lead-sheathed cable (*see* Fig. 1) built to Engineering Standards Committee specification will comply with the new Home Office Committee recommendation as to conductivity. Objection has also been taken in some quarters to bitumen insulated cables because of the action of alkaline waters (which often occur in mines) upon the prepared bitumen. To overcome this defect, the British Insulated & Helsby Cables have patented a cable, called the reinforced bitumen cable (*see* Fig. 2). In it the bitumen sheath is protected by a special sheath which is unaffected by water with an alkaline reaction.

On the Surface—To bring the electricity to the pit mouth, it is often not commercially possible to transmit it except by means of overhead wires of copper or aluminium. The necessary cables, if of considerable length, would be costly and the ground to be traversed is often difficult to cross. In many cases, therefore, the use of overhead wires is indispensable. They should always be protected at each end by kicking coils and lightning arresters, well earthed through a resistance to limit the discharge current and consequent rise in pressure. Wherever the section of overhead wire exceeds, say, 0·075 sq. in. of copper, it is possible to effect a saving by using stranded aluminium instead, because, *for the same current-carrying capacity*, although the area of aluminium conductor required is 67 per cent. greater than that of copper, it is only one-half as heavy.

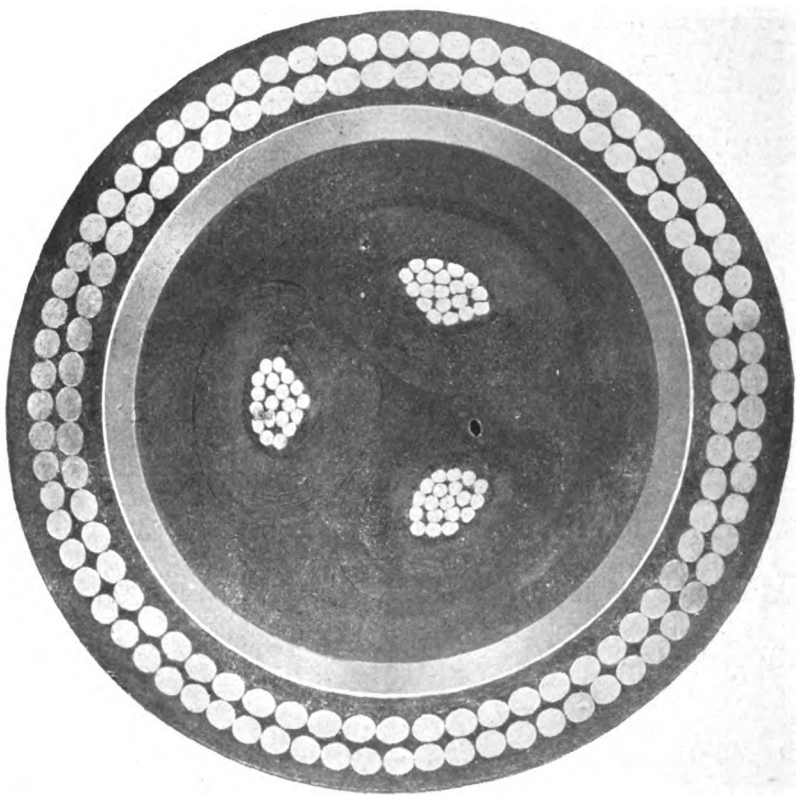

FIG. 1.—"BRITISH INSULATED" ARMOURED LEAD SHEATHED CABLE.

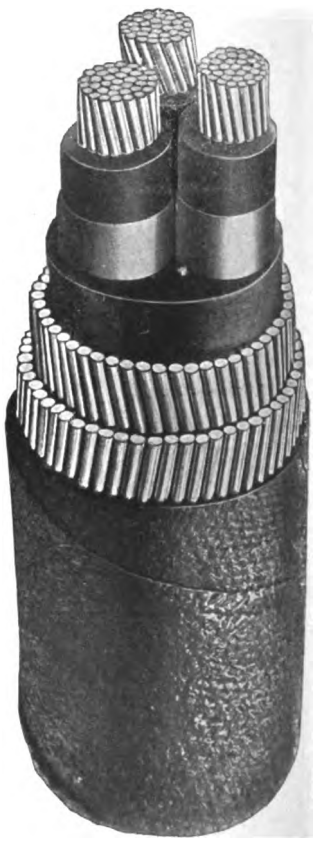

FIG. 2.—REINFORCED BITUMEN CABLE.

Fig. 3 shows a 3,000-volt three-phase line erected for the Weardale Steel, Coal & Coke Co., from Thornley to Wingate Collieries. The capacity of this line is about 1,000 H.P. The conductors are 19/10 aluminium, and the cost per mile is about £500. If insulated underground armoured cables had been used, the cost per mile, including trenching, would have been about £1,000.

Fig. 4 shows a 600-volt two-wire d.c. aluminium line erected for Newton Chambers & Co., from Rockingham Gas Works power house to Tankersley Park Colliery. Its capacity is about 550 H.P. The conductors are 1·4 sq. in. in section and are of aluminium. The total cost per mile of such a line is about £1,200. If equivalent copper conductors had been used

Digitized by Google

the cost per mile would have been about £1,800; had insulated and armoured aluminium cables been used underground the cost per mile would have been about £2,200.

These figures show very clearly the saving that can be effected by using overhead lines instead of underground cables; by using high-pressure lines instead of low-pressure ones; by using aluminium instead of copper. Aluminium conductors have, in fact, been extensively used for 10 years past in the United States and Canada for transmission line work, and in the United Kingdom it has been used, among others, by the War Office at Aldershot, the Glantawe Electric Supply Co. at Ystradgynlais, and the Fife Coal Co. Large insulated aluminium cables made by the British Insulated & Helsby Cables have been used underground by the Manchester and Bolton Corporations, who have nearly 11,000 yds. in successful use.

FIG. 3.—3,000-VOLT LINE FROM THORNLEY TO WINGATE COLLIERIES.

The British Insulated & Helsby Cables make, in fact, a speciality of the installation of cables in collieries and of the erection of transmission lines. The company has in hand, at the present time, contracts for both cables and overhead lines for continuous working at 20,000 volts alternating, and they have just laid, and put into service, several miles of single conductor cable for working at 120,000 volts direct-current on the Thury system.

The following are some of the pole lines they have in hand or just completed in connection with the transmission of power to collieries in addition to the two already illustrated: (1) From Black Fell Engine, about 1 mile from Birtley, to Harraton Colliery, Durham. The length of this line is 1½ miles, and the size of conductors 0·1 sq. in. copper strand. (2) From the Rising Sun Colliery, near Benton, to Backworth sub-station, Northumberland, a distance of 2 miles. (3) From East Holywell sub-station, for a distance of 2½ miles, to Seghill Colliery. The above three lines are working at a pressure of 6,000 volts and the conductors are arranged to form an equilateral triangle, the sides of which are 4 ft. long. (4) From Seaton Delaval sub-station, for a distance of 3½ miles, to Newsham sub-station, Northumberland. This line works at 11,000 volts. (5) From a point outside Wallsend to the Newcastle Electric Supply Co's Burradon sub-station, a distance of 3½ miles. This line works at 20,000 volts. (6) From Pelton to Shield Row Colliery, a

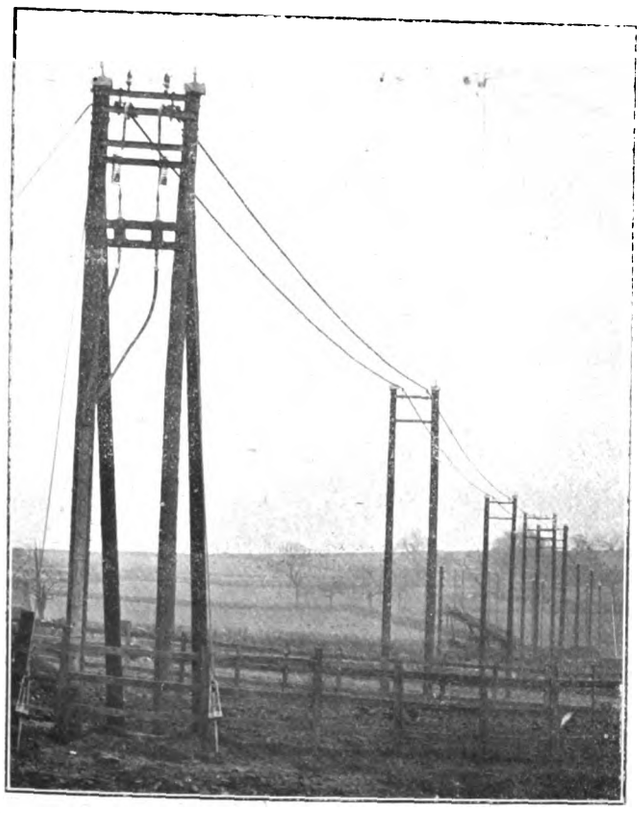

FIG. 4.—600-VOLT DIRECT-CURRENT LINE FROM ROCKINGHAM GAS WORKS POWER HOUSE TO TANKERSLEY PARK COLLIERY. ALUMINIUM WIRES.

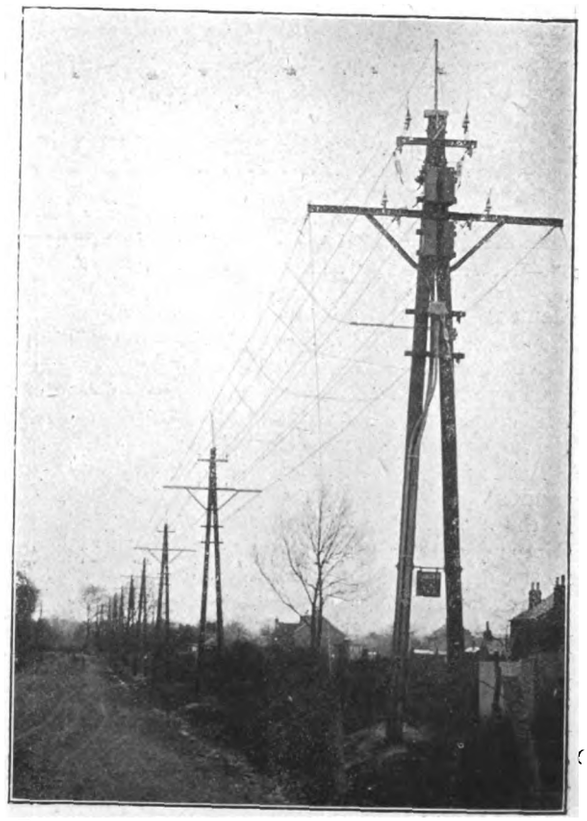

FIG. 5.—3,000-VOLT THREE-PHASE LINE, WITH ALUMINIUM CONDUCTORS.

Digitized by Google

distance of 2½ miles. The pressure of this line is 11,000 volts. (7) Ackley Head sub-station to Tater House Colliery via Framwell Gate Moor Colliery, a distance of 1¼ miles, alongside waggon ways. The voltage here is 6,000. (8) South Pelaw to Pelton Fell, for a distance of ½ mile. This line works at 11,000 volts.

Fig. 5 shows a 3,000 volt three-phase four-wire line with aluminium conductors, just completed for the War Office at Aldershot. On the terminal pole can be seen the method of connecting the underground paper-insulated wire-armoured cable to a terminal sealing box, and thence through kicking coils to the overhead line wires. The horn arresters are also shown. These are connected to earth through resistances which will limit the amount of current which can flow to earth in the event of a rise of pressure or lightning causing the arresters to flash over. The illustration also shows a good example of cradle guarding to catch and earth any broken high-pressure conductor.

Electric Winding for Collieries.

Electric winding in collieries is a subject which has been before colliery owners and colliery engineers for some time part and therefore some particulars of the electric winding plant recently put down at Messrs. Dunn & Stephen's South Kenmuir colliery will doubtless prove interesting, as this installation probably marks the commencement of a series of important changes which are likely to take place in the near future in several colliery districts.

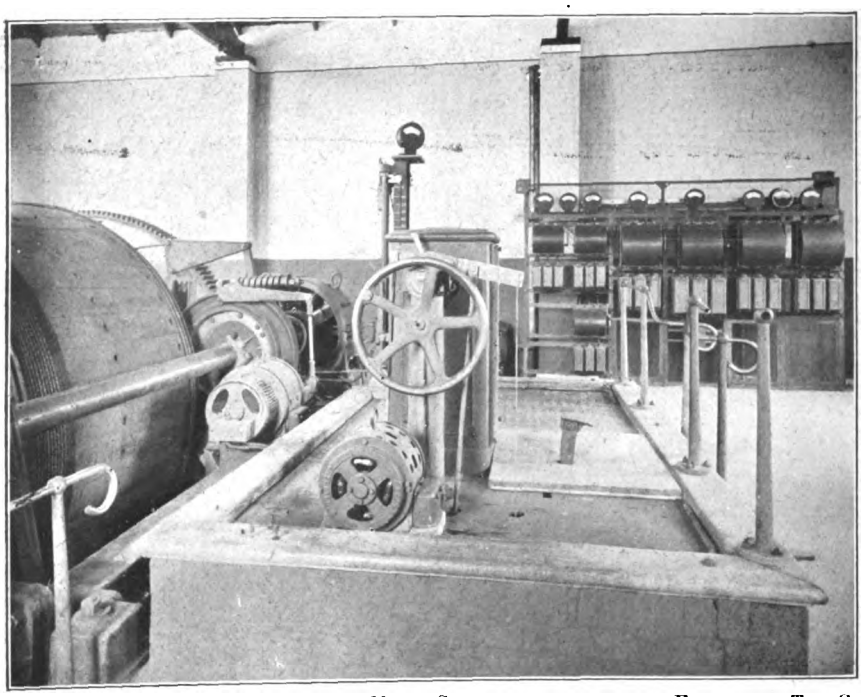

FIG. 1.—VIEW SHOWING BRAKE MOTOR AND MOTOR SOLENOID FOR OPERATING EMERGENCY TRIP GEAR.

It may be said that the advent of electric winding has been facilitated by the appearance in the colliery districts of the Power Supply Companies. The short hours now in force in most colliery districts also have a considerable bearing on the problem. Owing to these short hours the amount which has to be charged to the winding costs to cover depreciation and interest on capital is now a very considerable item, and the saving of a large proportion of these capital charges which is effected by taking electricity from the power company makes a considerable difference to the net cost per ton of raising coal.

The winding gear at Messrs. Dunn & Stephen's pit is designed for winding eventually from a depth of 160 fathoms though at present it is only working from the 90 fathom level. Each cage carries two hutches with a total of 17 cwt. of coal, the empty hutches being lowered in the other cage, and as a winding schedule of 65 winds per hour can be obtained the gear is capable of dealing with 55 tons of coal per hour.

The main winding drum is of the spiro-conical type, in which at the commencement of the wind the ascending rope is on a part of the drum, which has a diameter of approximately 5 ft., while the descending rope is on the centre of the drum whose diameter is 10 ft. This arrangement has the effect of minimising the effort required from the electrical plant during the period of acceleration, the rope being transferred to the part of the drum with the larger diameter towards the end of the accelerative period by a cast-iron spiral formed in the drum cheek. To this drum are geared two 105 H.P. continuous-current motors.

The electrical equipment is constructed on the well-known "C.M.B." system, which is manufactured by Messrs. Crompton & Co., of Chelmsford. This system involves the use of a motor-generator, which converts the three-phase alternating current taken from the Clyde Valley Electrical Power Co. to continuous current.

This motor-generator is further so designed that the characteristics of the continuous-current supply are exactly suited to the demands of the driving motors, so that a direct electrical connection may be made between this motor-generator and the

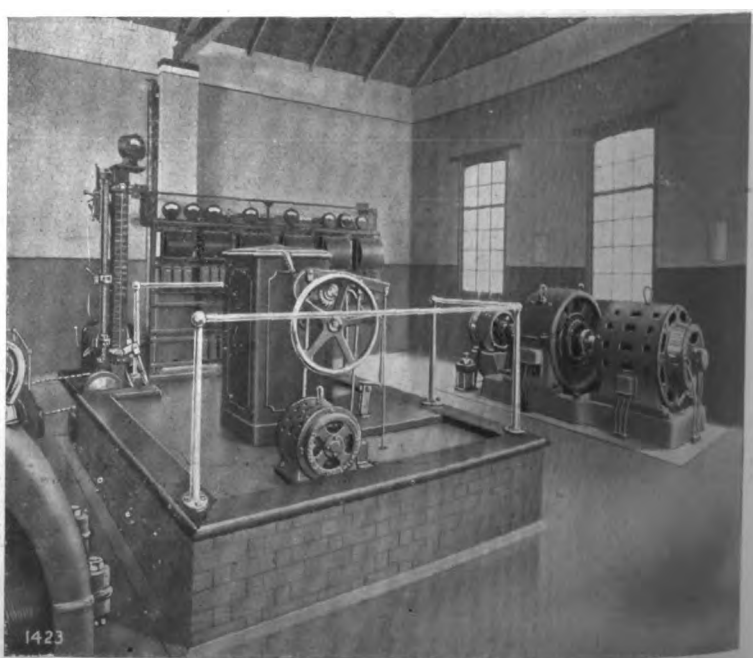

FIG. 2.—CONTROL PLATFORM AND "C.M.B." MOTOR-CONVERTER, SOUTH KENMUIR COLLIERY.

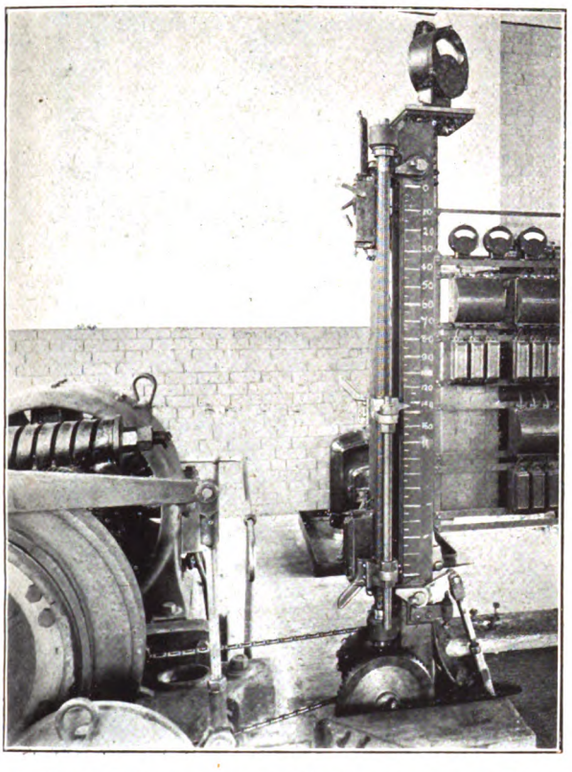
Digitized by Google

motors without the insertion of any controller or resistance, such as is common in most forms of electrical driving.

The motor of the motor-generator is of the Crompton standard type, with wound rotor and slip-rings for use in starting, a liquid starting resistance being employed. An ampere-meter and a voltmeter are provided in the alternating-current circuit, and a voltage coil is connected from the incoming leads to the emergency trip gear, which is connected to the brake. The above motor is coupled direct on the same bedplate to a continuous-current generator whose fields are wound with three coils in order that it may give a constant current characteristic. In circuit with the dynamo field is a shunt resistance of special type, which forms the principal controller. By it the dynamo voltage can be regulated from nothing to its maximum value. It is also provided with a special trip coil, which compels it to return to the "off" or "no voltage" position in the event of any of the trip switches opening c



IG. 3.—DEPTH INDICATOR SHOWING METHOD OF OPERATING LIMIT SWITCHES.

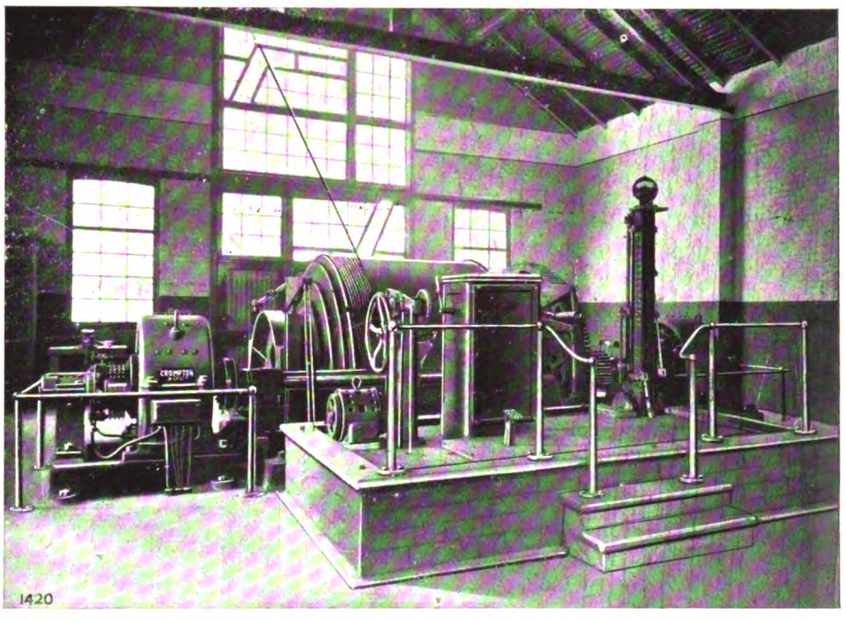


FIG. 4.—GENERAL VIEW OF WINDING PLANT AT SOUTH KENMUIR COLLIERY.

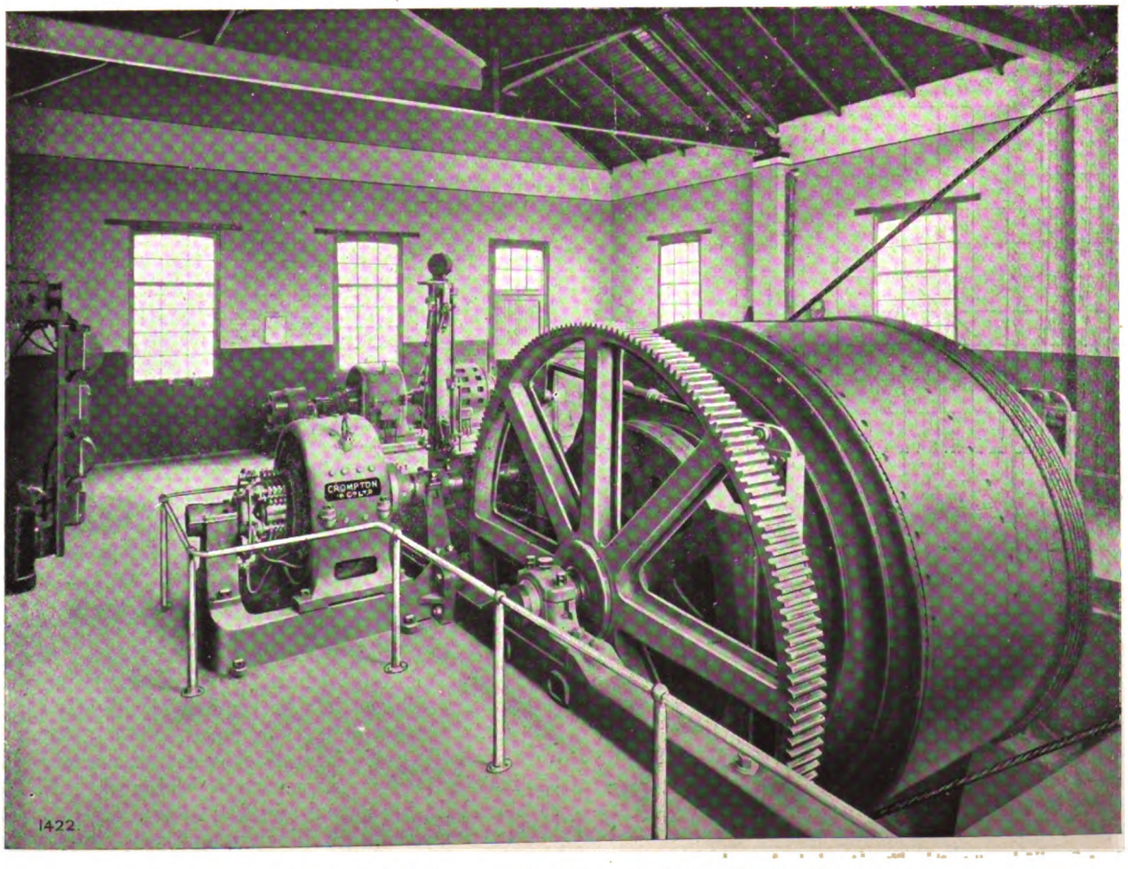

FIG. 5.—"C.M.B." WINDING EQUIPMENT AT SOUTH KENMUIR COLLIERY.

Digitized by Google

certain accidents occurring. A demagnetising coil is provided, which does away with the necessity for series resistances, as it automatically adjusts the dynamo voltage to whatever voltage may be required by the motors, no matter what the speed may be at which they are running. The two motors connected to the winding gear are fitted with specially wound field magnets.

The following table gives details of the operation of a "C.M.B." electric winding set :—

Retardation period	8 seconds
Banking period	10 ,,
Time required for each wind	55 ,,
Maximum winding speed	1,360 ft. per min.
Total weight of coal per hour	55 tons
No. of working hours per day	8 hours
Total weight of coal per day	440 tons
Capacity of motors	0–150 B.H.P.
Speed of motor	0–400 revs. per min.
Output of motor-generator	120 kw. at 0–400 volts
Supply circuit particulars	440 volts by 25 ∽, 3 phase

The combination of the motor generator and motor field windings, Messrs. Crompton inform us, give speed torque characteristics which are well suited to the requirements of the winding gear and to a restricted power demand ; thus it is possible, they claim, with this system to provide the heavy starting and accelerating torque with only a limited increase of power from the main circuit, to give natural speed variations changing from one set of conditions to another without any shock whatever either to the mechanical or electrical parts of the equipment, and to produce complete control of the gear by the movement of one switch, which is the regulator in series with the B coil of motor generator.

The mechanical gear is provided with two double shoe brakes of the usual type, which may be applied by foot power or by an emergency brake, which is released in the case of an overwind or the failure of the power supply through the agency of the trip coil. In addition to these brakes there is a working brake on the first motion shaft which is brought into operation to a small extent at the end of every wind. It is magnetically

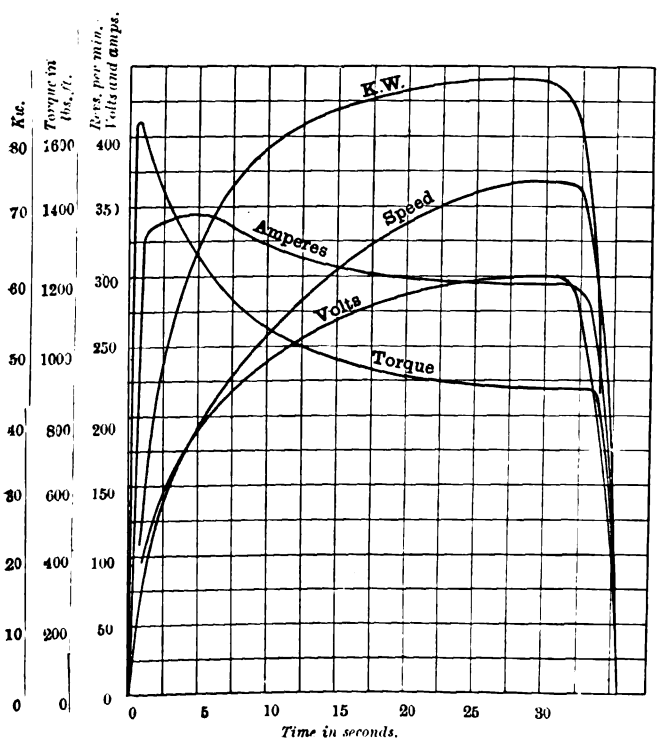

FIG. 7.—CURVES SHOWING THE OPERATION OF THE WINDING ENGINE AT THE SOUTH KENMUIR COLLIERY.

controlled by a motor. When stopping the cage the controller is gradually brought back, and the current through the field of the brake motor is decreased, so that the brake comes on quite gradually until the cage comes to rest. This brake also acts as a safety device, as it will come into action in the event of the exciting set losing its voltage or the exciter circuit being opened ; in the event of the motor circuit being opened, or of the motors running away and tending to return power into the motor-generator.

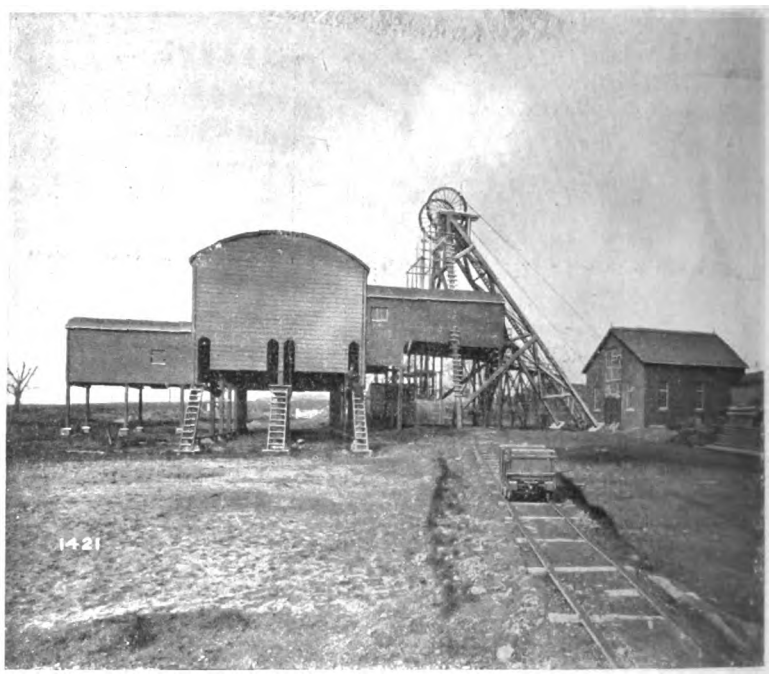

FIG. 6.—SOUTH KENMUIR COLLIERY, NR. GLASGOW, WHERE THE COAL IS RAISED BY THE "C.M.B." PATENT SYSTEM.

In order to reverse the direction of movement, a main circuit reversing switch is provided. It changes from one set of connections to the other without opening the motor circuit. By this arrangement the cages are always held in position electrically, for even while changing from one set of contacts to the other the armatures are short-circuited while the motor fields are fully excited.

Pilot contacts are provided on this reversing switch which are connected through the limit switches and the voltage coil on the controller of the motor-generator to the exciter voltage. These pilot contacts ensure that if the reversing switch is moved improperly at the wrong moment the controller will return to the "off" position ; the pressure of the motor-generator will fall to zero, and any tendency which there might be for sparking or excessive currents will be immediately negatived. These pilot contacts also work in conjunction with the limit switches, so that if one limit switch has been passed the reversing switch may be pulled over and the pilot switch will then make a circuit through the other limit switch, enabling the gear to be run in the other direction and the cages brought back into their place. The limit switches are worked by a depth indicator gear connected to the main winding drum, and an indicator is provided so that the driver may know the exact position of the cages at every moment.

It is estimated that the maximum demand for power from the supply circuit will not exceed 120 kw., and that the consumption of electrical energy per ton of coal will be approximately 1·5 units per ton raised. Assuming that electrical energy can be purchased at the rate of ¾d. per unit, the cost for power of winding coal from this depth is slightly less than 1·1d. per ton, a figure which, it is claimed, will compare very favourably with the cost of winding by steam, especially in view of the fact that only one man is required, and that he only needs to attend during actual winding hours.

The accompanying illustrations show various views of Messrs. Crompton & Co.'s winding gear at the South Kenmuir Collieries together with a curve giving the operation of equipment.

ELECTRIC WINDING ENGINES.

In the following Tables we give particulars of the electrically-driven winding engines at present in existence in various parts of the world. We cannot claim that these Tables are quite complete, though every care has been taken to make them so; but it will nevertheless be agreed that the entries are numerous enough to show what great progress has been made in the application of the electric drive to winding plant. A few years ago, had we given such a table, the entries would have been extremely meagre, now they amount to over 150. Yet there is an idea abroad that very little is being done in this direction. We have to thank the various makers mentioned in these tables for supplying us with the particulars given. Further details of some of these plants will be found in the article by Mr. G. Hooghwinkel on another page of this issue.

The Power and Telephone Equipment of the Llanharran Colliery.

The Llanharran Colliery, owned by the South Rhondda Colliery Co., is one of the latest to be electrically equipped throughout, and a short description of the cable system, embracing as it does power and telephone circuits, will, therefore, undoubtedly be of interest to our readers. For the details which we are enabled to furnish we are indebted to the courtesy of the consulting engineer, Mr. John Wayne-Morgan, and to the contractors. Messrs. W, T. Henley's Telegraph Works Co.

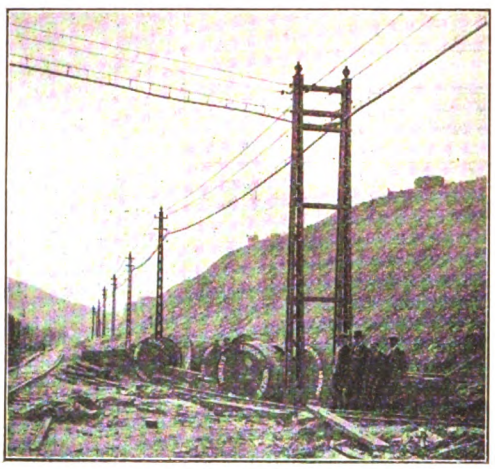

FIG. 1.—DOUBLE LATTICE POLE CONSTRUCTION AT LLANHARRAN COLLIERY.

The power installation is worked at a pressure of 2,200 volts three-phase, the frequency being 50. The cables above ground are carried on 31 ft. lattice poles embedded 4 ft. deep in concrete. These lattice poles carry a 0·09 three-core vulcanised bitumen wire-armoured cable on a 7/10 S.W.G. steel suspension strand, having a breaking strain of 80 tons per square inch, and they proceed from the generating station to a point where two 0·046 three-core vulcanised bitumen wire-armoured cables are tapped off. At this point a double lattice pole is provided, with a platform to hold the necessary "tee" junction box. This double pole is shown in the foreground of the accompanying illustration (Fig. 1), which was taken while the work was in progress. One of the 0·046 cables is carried on further lattice poles to the motor house of the brickyard about 210 yds. away, and the other is connected with the washery, being supported on brackets fixed to the washery screen girders. The lattice poles are fitted with brackets to carry the telephone cables, and cross arms to take the lighting and suspension wires. The cables are suspended with Henley's patent cable suspenders throughout.

FIG. 3.—AT THE PIT HEAD.

For supplying power in the workings a 0·2 sq. in. three-core vulcanised bitumen wire-armoured cable is carried from the generating station to the pit mouth on similar lattice poles to those already referred to. Thence it is held by a clamp at the head and by cleats to the side of the shaft, and is carried to a sub-station at the pit bottom. We show an illustration (Fig. 5) of the 0·2 sq. in. cable suspended. The section of cable, suspenders and suspension strand are all shewn half size. We also give illustrations, very much reduced (Figs. 2 and 4) of the clamp and cleats used, the latter being fixed

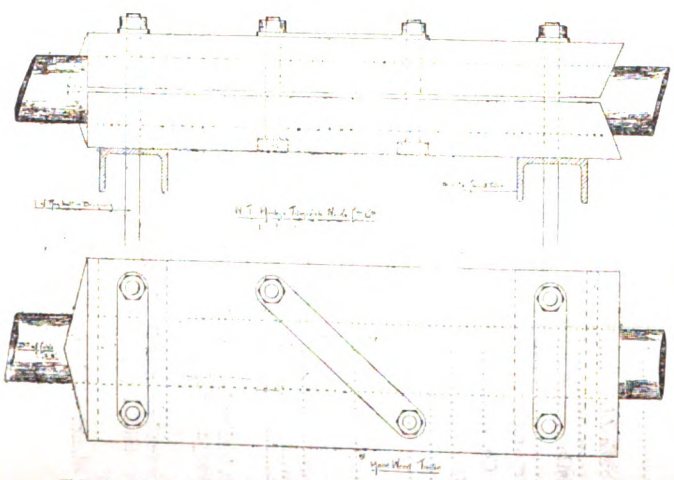

FIG. 2.—CLAMP USED AT LLANHARRAN. (Illustration very much reduced.)

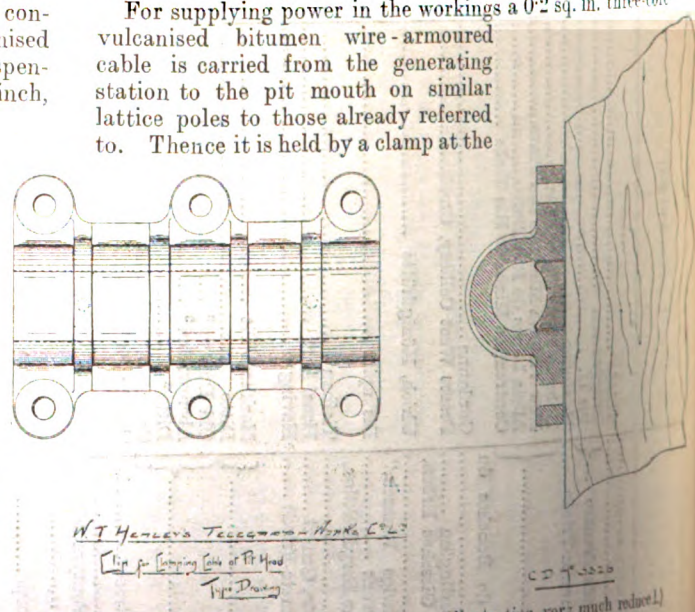

FIG. 4.—CLEAT USED AT PIT HEAD. (Illustration very much reduced.)

Digitized by Google

30 ft. apart in the brickwork of the shaft. From the sub-station vulcanised bitumen three-core wire-armoured cables, suspended to the timbering by eye-bolts and Henley's

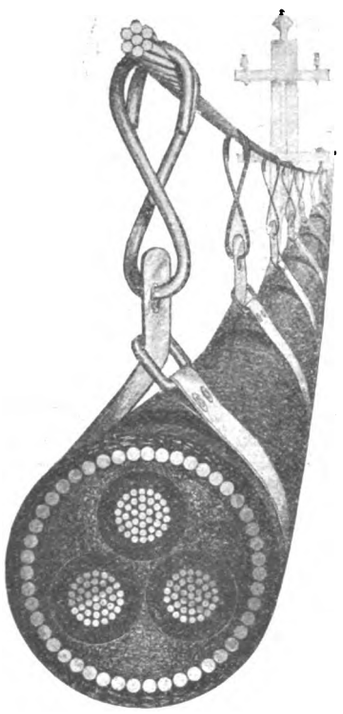

FIG. 5.—0·2 SQ. IN. CABLE, 7/10 STRAND AND HENLEY PATENT CABLE SUSPENDER. All shown half-size.

patent cable suspenders, connect with various districts as follows: a 0·066 sq. in. cable to a pump room 1,050 yds. distant and a 0·0229 sq. in. cable from this pump room to another 150 yds. further on; a 0·066 sq. in. cable to a second district 1,100 yds. away, and from thence a 0·0128 sq. in. to a pump room 150 yds. further on, and a 0·035 sq. in. cable to a third district 400 yds. away. The whole of the armouring and suspension wire is efficiently bonded and earthed by means of a copper earth plate at the generating station end. Fig. 3 shows the cable about to be laid.

In addition to the power equipment a complete telephone installation has been erected. This is a 10-way system, the switchboard being in the generating station. It connects the generating station, offices, brickfields, washery, the sub-station at the shaft bottom and three points in the workings, thus allowing two spares, one above and one below ground. The telephone cables are carried on the lattice poles above ground, are cleated to the side in the shaft, and suspended in the workings from eye spikes by means of Henley's patent cable suspenders (Fig. 5). The cables are five pair No. 18 S.W.G. paper-insulated, vulcanised bitumen sheathed and wire-armoured for the above-ground ramifications to the sub-station at the bottom of the pit, and 18 S.W.G. twin cables of similar construction to the several points in the workings.

Various types of telephones are installed to suit the different situations, those below ground being battery ringing waterproof mining telephones. The whole of the parts in the latter type are fitted in a cast-iron waterproof case provided with a stuffing gland through which the line wires are lead. The bells in connection with these instruments are of the gas and watertight type. The terminals are fitted inside the iron case, which is provided with stuffing glands for the wires, and the motion of the armature is transmitted to the hammer through a metal diaphram. When the cover is screwed down the whole of the movement is enclosed in an hermetically sealed chamber, rendering it impervious to atmospheric influences.

Messrs. Henleys supplied and carried out the whole equipment, including cables, lattice poles, telephones, switch panels, boxes, cells, &c.

Pumping Plant for Mines.

At the present time there is considerable rivalry between the centrifugal and reciprocating types of pump for mining work, and it is therefore of interest to compare some of the more recent installations of both types of pump in collieries. Generally speaking, the ram type of pump is most suitable for positions where it is required to raise a comparatively small quantity of water to a considerable height. On the other hand, a centrifugal pump, owing to its low first cost and the small space it occupies, is more suitable when large quantities of water have to be raised against comparatively low heads.

Messrs. Ernest Scott & Mountain, of Close Works, Gateshead are a firm that have had considerable experience in the manufacture of both classes of pumping plant, and they have recently carried out several large installations employing one or other of these types. A particularly interesting

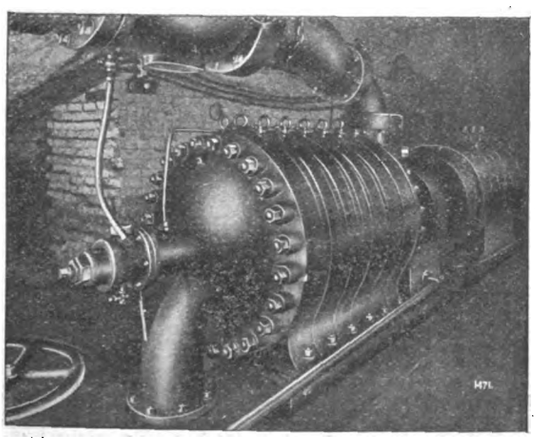

FIG. 1.—AN EARLY CENTRIFUGAL PUMPS AT A DURHAM COLLIERY.

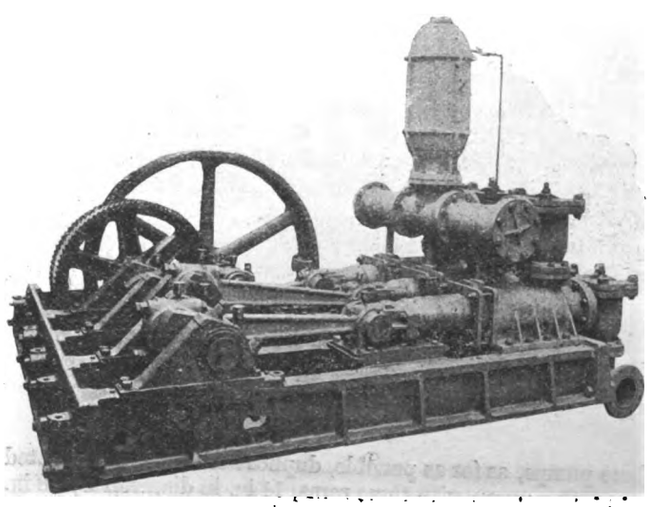

FIG. 2.—ONE OF THE NEW RAM PUMPS AT THE SAME COLLIERY.

Digitized by Google

installation of ram pumps has recently been supplied to a colliery in the county of Durham, the original equipment in this case consisting of centrifugal pumps. There were two sets of pumping plant, one made up of two units each designed to raise 1,200 gallons per minute against a 690 ft. head, and the other made up of two similar units arranged to deliver 750 gallons per minute against 950 ft. head. The centrifugal pumps which were of Messrs. Scott & Mountain's manufacture, dealt quite satisfactorily with these duties: but after they had been running for some time it was found that the wear and tear on the internal parts was excessive, while investigation showed that the water contained a considerable amount of impurities.

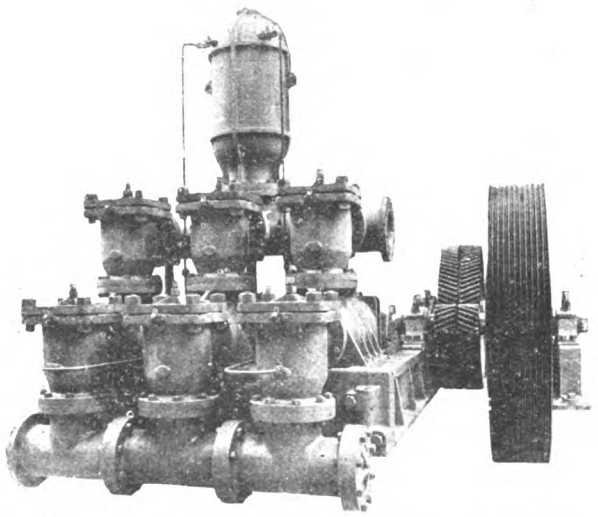

FIG. 3.—ANOTHER VIEW OF THE SAME PUMP, SHOWING THE VALVE BOXES.

After running for some years, the colliery company decided that the conditions were not suitable for working with centrifugal pumps, and it was therefore decided to instal one ram pump in each position, and to keep one of the centrifugal pumps in each case as a standby. In Fig. 1, one of the original centrifugal pumps with its motor is shown. The motors were of the three-phase type, working on a 2,750-volt circuit with a frequency of 40 supplied from the County of Durham Supply Co.'s mains. Each motor exerted 375 effective H.P. when running at a speed of 1,160 revs. per min.

The order was placed with Messrs. Scott & Mountain for two ram pumps for the duties stated, and it was arranged to make these pumps, as far as possible, duplicates. The sizes adopted were: One pump with three rams, 14 in. in diameter by 18 in. stroke, delivering 900 gallons per minute against 690 ft. head, and one pump having three rams, 11 in. in diameter by 18 in. stroke, delivering 550 gallons per minute against 950 ft. head. By keeping the stroke the same in the two pumps it was possible to duplicate a very considerable proportion of the two pumps, this being the case with the bed plate, crankshafts, connecting rods, gearing, bearings, &c. A general view of one of these pumps is shown in Fig. 2, and a further view of the same pump taken from behind the valve boxes is shown in Fig. 3. These pumps are of the makers' standard type, being fitted with solid gunmetal rams, with gunmetal glands and stuffing boxes, and provided with independent and interchangeable ram chambers and valve boxes. The arrangement is clearly shown in Fig. 3, and it will be seen that the whole of the valve boxes on the suction and delivery sides are interchangeable. A large air vessel is fitted on the delivery side, and a special air charging device is provided, of a type introduced by Messrs. Scott & Mountain. This device consists of two pipes led from the outer rams to the air vessel, and so arranged that on each stroke of the pump a small amount of air is fed into the air vessel, and thus all possibility of the air vessel becoming solid with water, is avoided. The pumps in both cases were arranged for rope drive between the pump and motor, and between the pump countershaft and crankshaft, machine cut helical gearing was provided.

FIG. 5.—3,000-GALLON CENTRIFUGAL PUMP.

In the makers' opinion this class of driving is most suitable where sufficient space is available, as, with high class machine cut gearing such as this, there is practically no noise, and the rope drive of the motor prevents any vibration reaching the electrical gear, the whole combination forming a most elastic and suitable drive. It is, however, not always possible to obtain space for this arrangement, and in Fig. 4 a similar pump set is shown to the foregoing, but provided with a gear drive from the motor and having the pump bedplate extended to carry the motor. This pump was also installed recently in a colliery in the county of Durham.

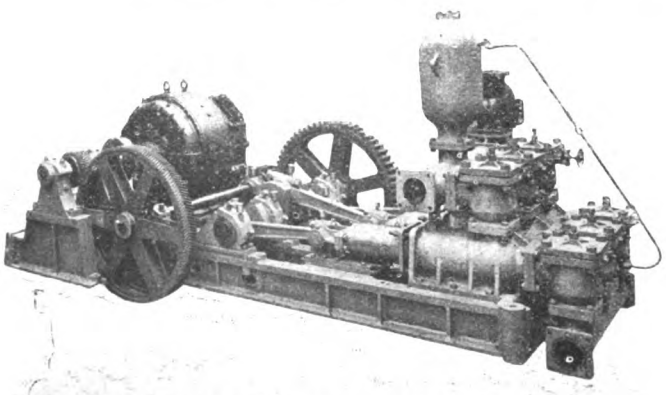

FIG. 4.—RAM PUMP AND MOTOR ON THE SAME BED PLATE. MOTOR DIRECT COUPLED.

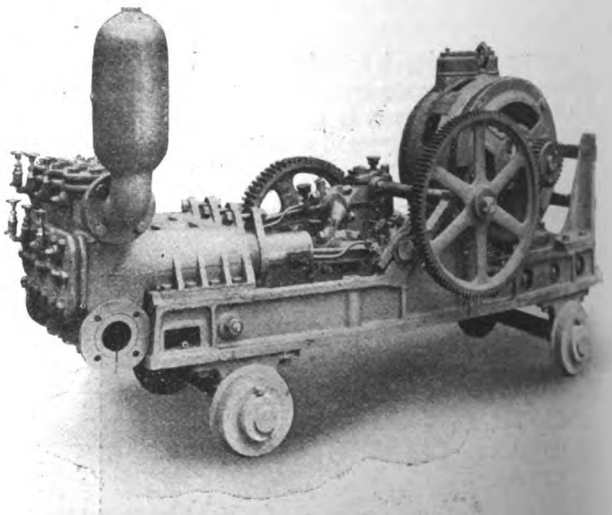

FIG. 6.—PORTABLE RAM PUMP.

Digitized by Google

These illustrations and descriptions indicate briefly what may be considered the latest practice in ram pumps for colliery work, and undoubtedly the pumps described are the most suitable class of machinery for dealing with severe conditions. On the other hand, there are a large number of collieries in which it is possible to pump a considerable quantity of water against low heads, and in such cases the centrifugal type of pump is making very rapid advances. The same firm have recently completed a large centrifugal pump for a colliery in the Newcastle district, to deliver 2,500 gallons per minute against a head of 170 ft. This pump is being installed to replace an existing steam pump, which is at present working practically constantly, but the new pump is of sufficient capacity to do the whole of the work in approximately six hours per day, exclusive of week ends. A very considerable saving can be effected by this means, and a large number of collieries are at present considering such pumping schemes with a view to performing the whole of the pumping in one 8-hour shift, as, of course, under the new Eight Hours Bill it is necessary to provide two or three shifts of pump attendants if this time is exceeded.

The pump in question is of particularly massive construction, and is run at the very moderate speed of 800 revs. per min., this speed being decided upon as the pump has to be worked without a standby, and it was desired to reduce the wear and tear of the parts to a minimum. The pump is of the makers' latest standard type, and is arranged so that the whole of the working parts, that is the impellers and diffusers, can be withdrawn for inspection or repairs without interfering with either the delivery or suction pipes. The pump is of the two-stage type, and is fitted with a special type of balancing disc to compensate for the end thrust due to the pull on the suction side. The motor driving the set is of the direct current type, supplied with current at 480 volts from the Newcastle-upon-Tyne Electric Supply Co.'s mains, and is arranged to develop 200 H.P. constantly at a speed of 800 revs. per min.

In Fig. 5 a somewhat similar pump is shown, this set being arranged to deliver 3,000 gallons per minute against a 200 ft. head. It was constructed for a colliery in the same neighbourhood. This pump is of the double inlet type, and is provided with two impellers placed back to back so that the end thrust of the suction is balanced. It is arranged to run at a speed of 1,160 revs. per min., and is driven by a three-phase motor worked on a circuit with a frequency of 40.

The above illustrations and descriptions exemplify a few of many such installations which are at present being carried out in various parts of the country, and serve to show the general practice for main shaft pumping by means of electricity in collieries.

There is also at the present time a considerable demand for similar electrically driven portable pumps for dip working, and the advantages obtained by the use of electricity in this class of work are even more marked than in the case of main shaft work, as it is practically impossible to obtain steam in remote places, and the losses on compressed air working over considerable distances are extremely heavy. In Fig. 6, a pump set arranged for this class of working is shown. These pumps are usually required for heads not exceeding 200 ft., and for quantities of water varying from 10 up to 200 and 300 gallons per minute. They form an extremely compact unit, the pump, motor, and motor switchgear being all mounted upon a common bedplate which in turn can be mounted on trolley wheels if desired. Centrifugal pumps have also been adopted for this type of working, but are not so suitable owing to the fact that a centrifugal pump only works economically when delivering against the particular head for which it is designed, whereas the ram pump is not affected to any appreciable extent by variations in head.

Some Cable Makers' Problems in Mining Work.

The following remarks deal very briefly with some of the more salient features which face the cable maker in catering for colliery work. They have been kindly supplied us by Messrs. W. T. Glover & Co., of Trafford Park.

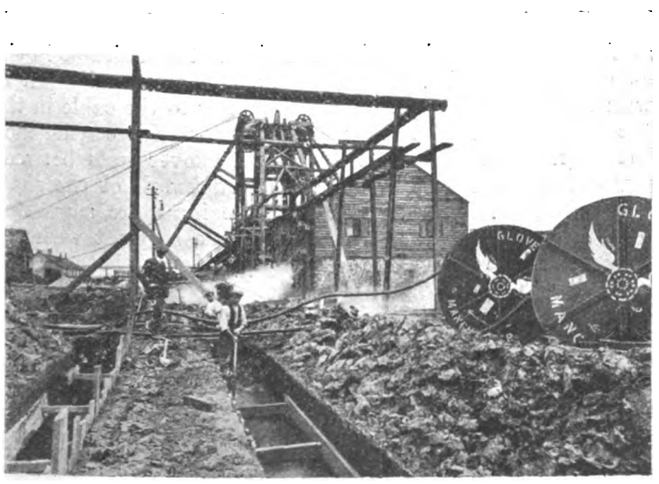

FIG. 1.—PREPARING TO LAY SURFACE CABLES SOLID.

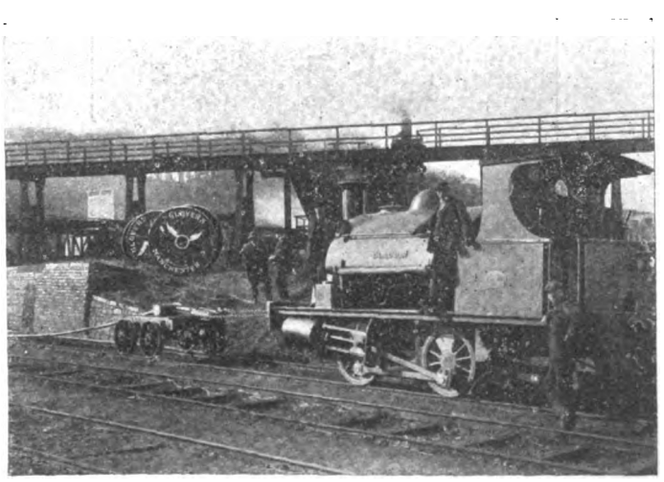

FIG. 2.—LOWERING SHAFT CABLE BY MEANS OF LOCO.

Firstly, as regards the type of cable which has come most prominently into use during the last few years. In the opinion of Messrs. Glover, the general trend has undoubtedly been to instal cables of the bitumen type, supplied in their own case in nearly all instances with patent solid filled strand (Fig. 3). For shaft work this firm have for long advocated the use of double wire armoured, in preference to unarmoured or steel tape armoured, conductors, thereby anticipating in this, as also in their strong advocacy of more mechanical, though possibly more expensive, accessories, the lines laid down in the

Digitized by Google

recent report of the Home Office Departmental Committee. Not only does wire armouring lend itself to much more effective bonding at the joints, but in case of serious leakage it provides a path to earth of a much greater area than that supplied by a double tape. Generally speaking the only troubles met with on the above class of cable have been due to the application of excessive heat, owing to the presence of steam pipes or vents in close proximity. In most cases troubles of this description

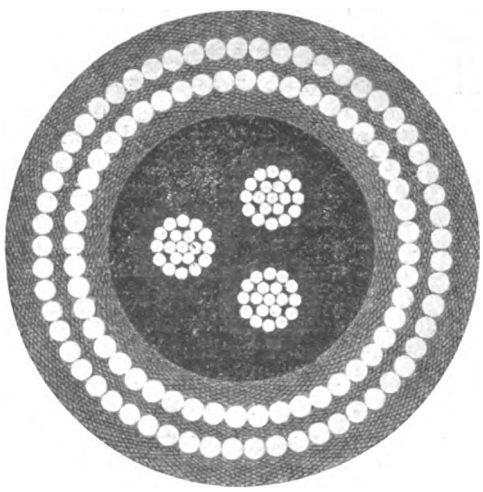

FIG. 3.—THREE-CORE BITUMEN CABLE WITH SOLID FILLED STRAND

have been confined to surface work, and to avoid running through the steam-saturated ground which is usually present in the vicinity of colliery workings, many managers are now arranging either to carry their surface conductors overhead or to lay them in trenches in the manner depicted in the accompanying illustration (Fig. 4), such trenches, of course, being readily covered with checkerplate where their being left open would constitute a danger. Fig. 1 shows trench being prepared for cable about to be laid solid.

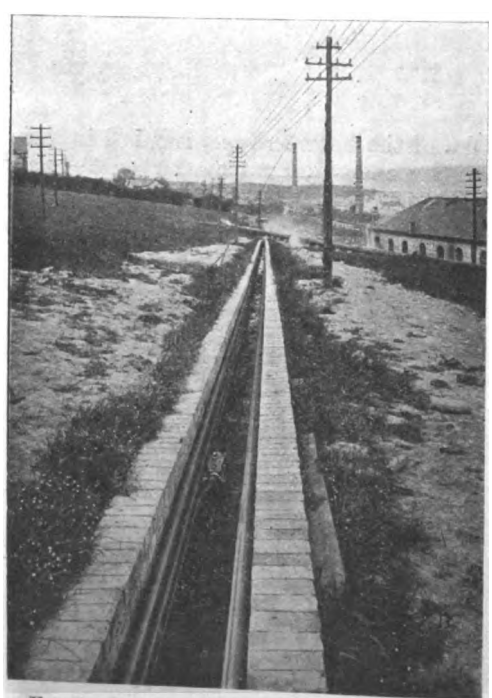

FIG. 4.—PERMANENT SURFACE CABLE TRENCH.

The great resisting power of wire armouring to falls is borne out in the case of the late deplorable disaster at the Pretoria Pit, where Glover wire-armoured cables of the paper and lead-covered type lay throughout the entire length of the North Plodder district under falls which have probably never been surpassed. The armour of these cables, though bruised, has in no place been severed, and we understand that the cables are now being re-slung without it being necessary even to take them to bank for examination or repair.

The second great question which confronts the mining electrical engineer is that of shaft suspension. Obviously no definite rule can be laid down, as much depends on local conditions; but there is little doubt that of the various methods employed, such as single suspension, double wire rope suspension, cleating with rag bolts, cleating with short chains or clamping by sitting cleats, the last named is, under average conditions, much the most satisfactory. Single suspension can, in fact, only be advocated where there are grave reasons for having no fittings of any kind in the shaft, and where the cages have rope guides. The greater the weight of the cable borne by its armour on one single fitting the more risk there is of a pinching stress on the dielectric, which experiments have shown to be most acute at a point about 12 in. below the suspending apparatus.

To clamp wooden cleats between two suspended steel hawsers, although it gives all the flexibility of direct single suspension, possesses the disadvantage of unequal expanding and contracting ratios between such wire ropes and the cable. To support wooden cleats by rag bolts or by short lengths of chain depending from the sides of the shaft is to set up a shearing

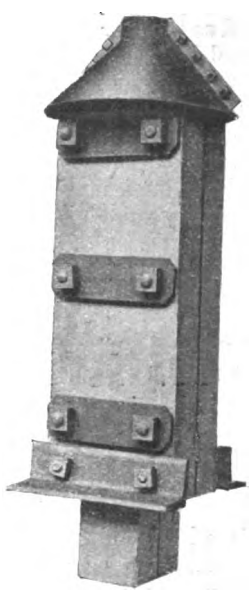

FIG. 5.—SITTING CLEAT.

FIG. 6.—LIGHT TYPE SUSPENDER FOR IN-BYE CABLES.

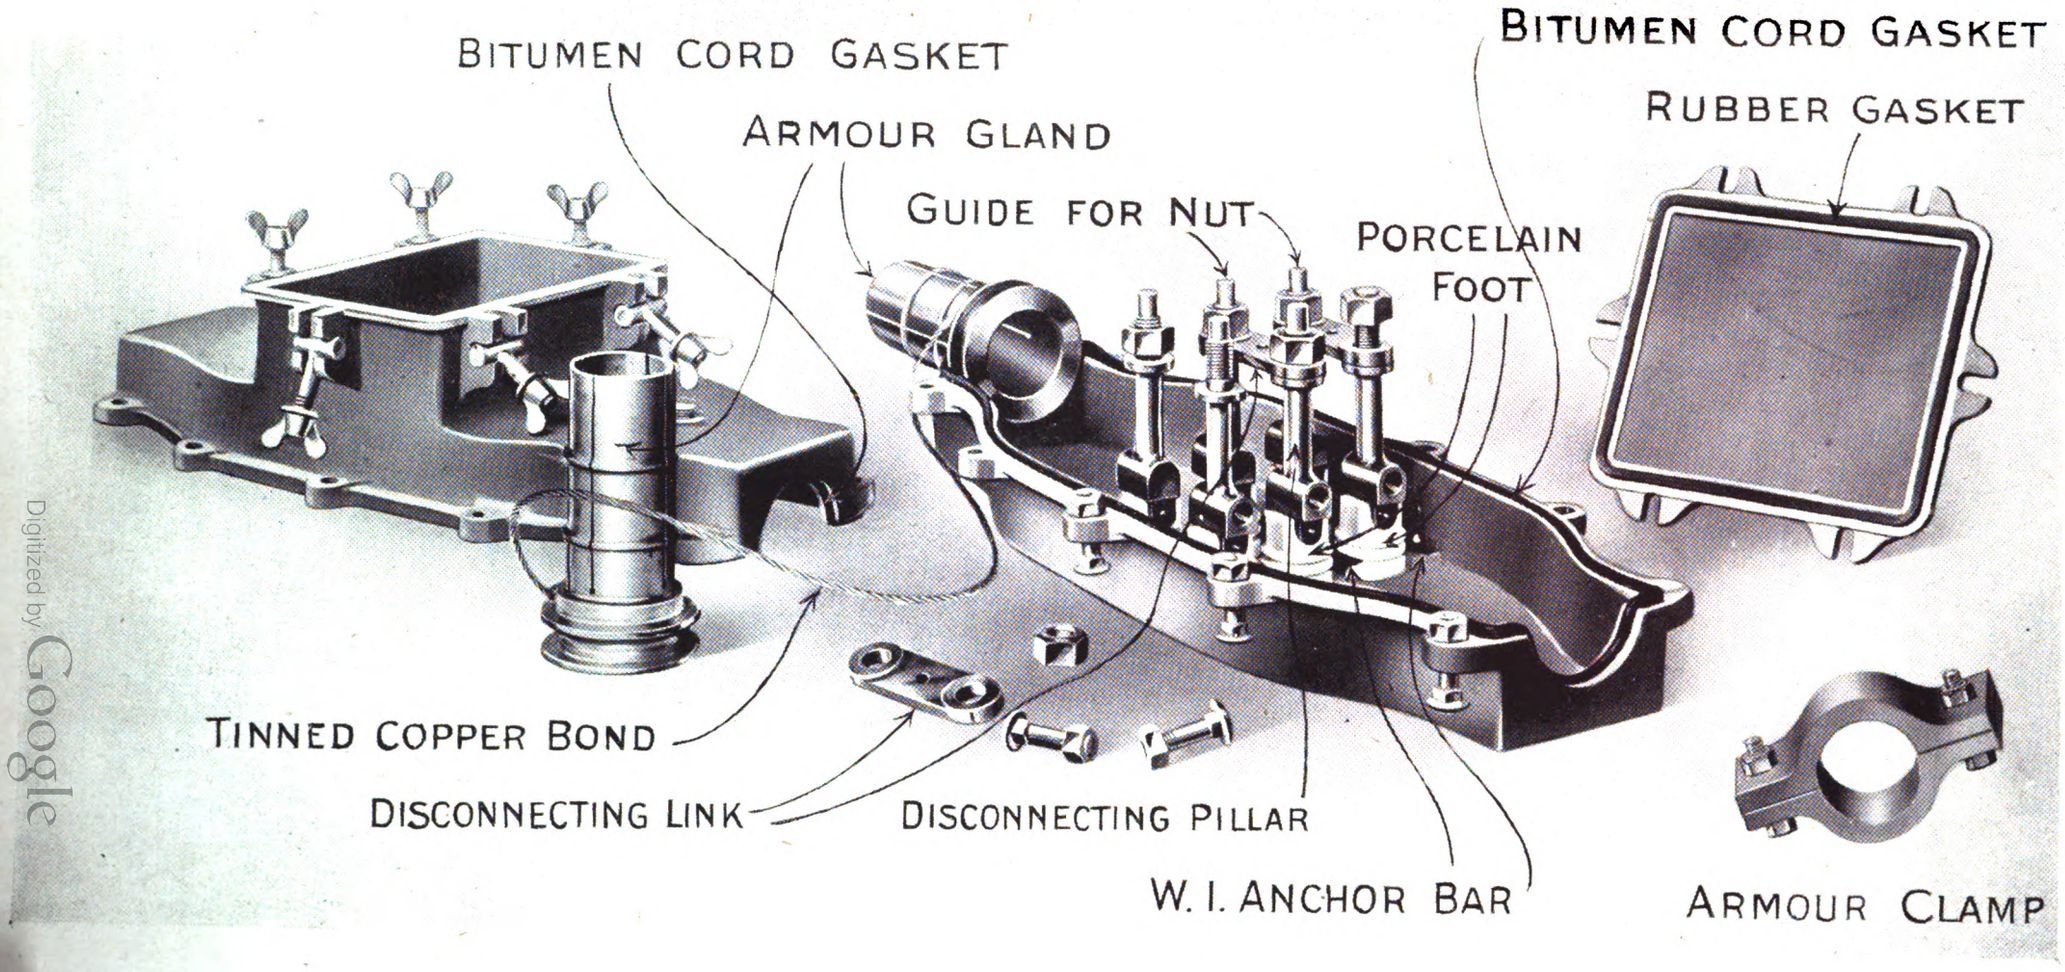
FIG. 7.—HEAVY TYPE SUSPENDER.

strain on the supporting bolts which is most undesirable in the case of falling bodies. These short chains are usually put in with the idea of giving a certain flexibility to the cable in the event of such mishap. To provide against this contingency the sitting cleat advocated by Messrs. Glover rests between two channel irons coming out of the brickwork of the shaft at right angles. The outer ends of the irons are supported on a large channel or H girder forming a segment with the curvature of the shaft, into the brickwork of which both its ends are built. The individual cleat should be from 2 ft. 6 in. to 4 ft. long, designed on the principle of a friction clutch. It should not embody a pinching grip—that is to say, the hole should be bored out to the exact diameter of the cable, and after the cleat has been cut through the saw cut and planing up of the two halves should allow $\frac{1}{4}$ in. clearance, a space which will amply provide a firm hold. For an average size of cable such cleats as the above may be conveniently spaced from 25 yds. to 35 yds. apart.

Means of actually lowering the cable into position are so many and varied as to be impossible of description here. Much depends on the time during which winding can be stopped, on the size of the cage and the diameter of the shaft. Given favourable conditions, perhaps the easiest method is to lower

Digitized by Google

GLOVER'S PATENT BOXES
WILL WITHSTAND HYDRAULIC PRESSURE.



Digitized by Google

a steel rope to which the cable is attached, say, every 15 ft., with hemp lashings. The slowness of this operation can be reduced by rigging up various stagings at equal distances from the pit head, on which men can carry on the lashing process simultaneously. Much can be said for other methods, such as raising from pit bottom, lowering from under or from inside the cage. On several occasions Messrs. Glover inform us a locomotive has been used to do the work (Fig. 2).

After lowering a cable into the shaft it is advisable to let it adjust itself to the new temperature conditions before finally cleating it up. As an additional aid to the friction of the grip

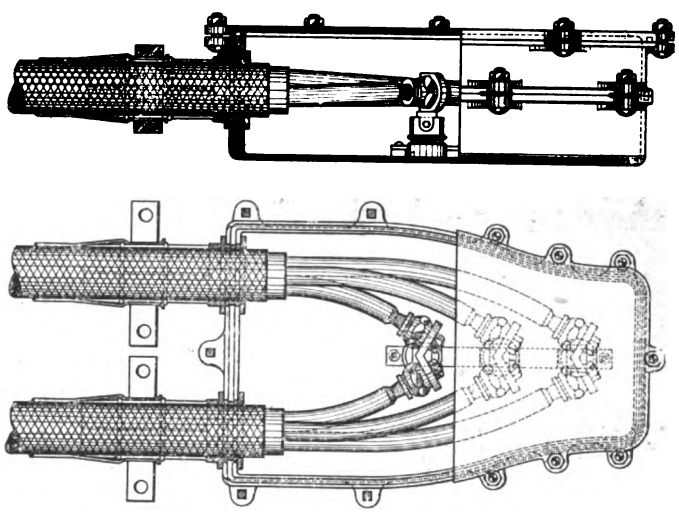


Fig. 8.—Horizontal Box for Shaft Cables.

it is advisable to wrap the cable inside each cleat with proof tape. Water and falling bodies can be further guarded against by providing the top of the cleat with a wrought-iron roof bolted together in two halves, as in the accompanying illustration (Fig. 5).

The question of jointing, whether in the shaft or inbye, is one of the utmost importance, and Messrs. Glover have experimented widely with a view to attaining the best practice in this direction. For shaft work a vertical box of any description is to be deprecated. Except where extensive tubbing exists, it will generally be found that the headings to various seams can be utilised as convenient recesses for the installing of horizontal boxes which will convey no strain to the incoming and outgoing cables, while they are protected from anything getting adrift in the shaft. Should no such

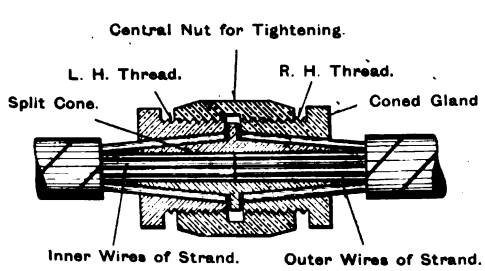

Fig. 9.—Patent Mechanical Connector.

heading exist, a recess can be readily built into the brickwork. An illustration of a box of this description is shown (Fig. 8). Its salient features are absolute water and compound tightness, long bearing and bonding surfaces at the glands, a very sound type of mechanical connector (Fig. 9) to join up the strands in places where it is unsafe to sweat, and porcelain feet supporting the connectors, which feet are themselves anchored by a wrought-iron strap to the carcase of the box.

Split boxes are provided with grooves top and bottom, carrying bitumen cords. These cords, under compression, unit in such a way as to make leakage a physical impossibility. Compounding, especially when the presence of heat cannot be permitted, is effected by the use of insulating mediums of low melting point, carried into the mine in vessels packed with sawdust and poured into the joint through a funnel, patented by Messrs. Glover, fitted with an external heating jacket.

The very vital point of earthing all machine carcases and switchboards below ground through the medium of the armour has been anticipated on all work carried out by Messrs. Glover for some years identically on the lines laid down by the recent Home Office suggestions. The means of earthing advocated at bank are never to rely entirely on buried earth plates, which, being out of sight, are soon forgotten, and which, if efficient (that is, surrounded by breeze in a moist position), will, through their very effectiveness, last but a very short time. They have made it a point for some years to carry heavy bonds from the armour sheathings at the supply end to not less than three lugs bolted to the flanges of cast-iron water pipes, which are never empty of water.

Armour has always been advocated for roadway or inbye cables, and special suspenders have been designed of an almost indestructible canvas material to take the place of the perishable pig-skin suspenders, with their accompanying eyelet difficulty, generally used for such cables a few years ago. The illustration (Fig. 6) shows this light type of suspender, in which the non-resisting portion, recommended by the Home Office to cater for falls, is embodied in the 8-shaped link, which is manufactured in such thicknesses of galvanised wire as will only just carry the weight to be borne, drawing out when any excess occurs. A heavy type of sling (Fig. 7) is also shown for use on suspension work in the neighbourhood of coke ovens. Protective devices form too big a subject to enter into in a short article, but a very effective gate-end arrangement, known as the "Fisher-Reyrolle" device, is supplied by Messrs. Glover. This is described in the article on "Coal Cutting," by Mr. H. J. Fisher, which appears in another part of this issue.

Recording Tachograph for Winding Engines.

One of the types of recording tachograph on the English market is that made under Dr. Horn's patents for use in connection with winding and hauling engines. These tachographs work on the double-weight spring-controlled centrifugal principle. On either side of the driving spindle are two weights connected in pairs by diagonal rods. These rods are pivotted on the spindle and are kept in an almost vertical position by means of a spiral spring the ends of which are fixed to each of the diagonal rods. When the spindle revolves, the weights move into a position more or less horizontal, which is determined by the speed at which the spindle is revolving. This motion is transmitted to a small plunger which can move up and down inside the spindle and which revolves at the same speed as the spindle. Inside this plunger is a small ball fixed to the end of the rod connection to the pointer and recording pen. It will thus be seen that the actual rubbing connection between the moving and stationary parts presents a very small surface and in consequence vibrations are reduced to an absolute minimum. A special form of damper is fitted to eliminate the very small variations that are always present, and therefore an absolute variationless sitting of the pointer and needle is said to be ensured. The recording drum of this instrument is fixed inside the casing, on the top of which is the dial. This drum is arranged vertically so that any portion of the record can be seen through the inspection glass. The chart is made to revolve by means of clockwork and the drum itself is lowered as it revolves, the record itself thus appearing spiralwise on the chart.

CARNEY & PEARN TRANSFORMERS

Combine High Electrical Efficiency with Sound Mechanical Construction.

The losses are small; the regulation on both inductive and non-inductive circuits close; the heating is uniformly distributed and the temperature rise under continuous full load, low, while the overload capacity is large.

The windings are mechanically braced to withstand abnormal stresses.

Made in all Types for all Services (up to 100,000 volts.).

Switchboards of the New Kleinfontein Consolidated Gold Mining Co.

As has been pointed out in other parts of this issue, not the least important part of the mining electrical equipment is the switchgear. In its design certain conditions have to be fulfilled in order that the operation of the whole plant may be satisfactory. The following brief description of the high-tension and extra-high-tension switchgear, supplied by Messrs. Ferranti Limited, for controlling the electrical power apparatus at the group of mines worked by the Kleinfontein Syndicate will enable our readers to determine how far this has been accomplished in this instance.

The main generating station of the group is situated at New Kleinfontein, from which the sub-stations, five* in number are fed by overhead transmission lines, the system employed being three-phase, and the pressure 20,000 volts. The switchgear in the main generating station is designed with a view to controlling eventually six three-phase generators working at 3,000 volts, six three-phase transformers stepping up the pressure from 3,000 to 20,000 volts and six out-going overhead

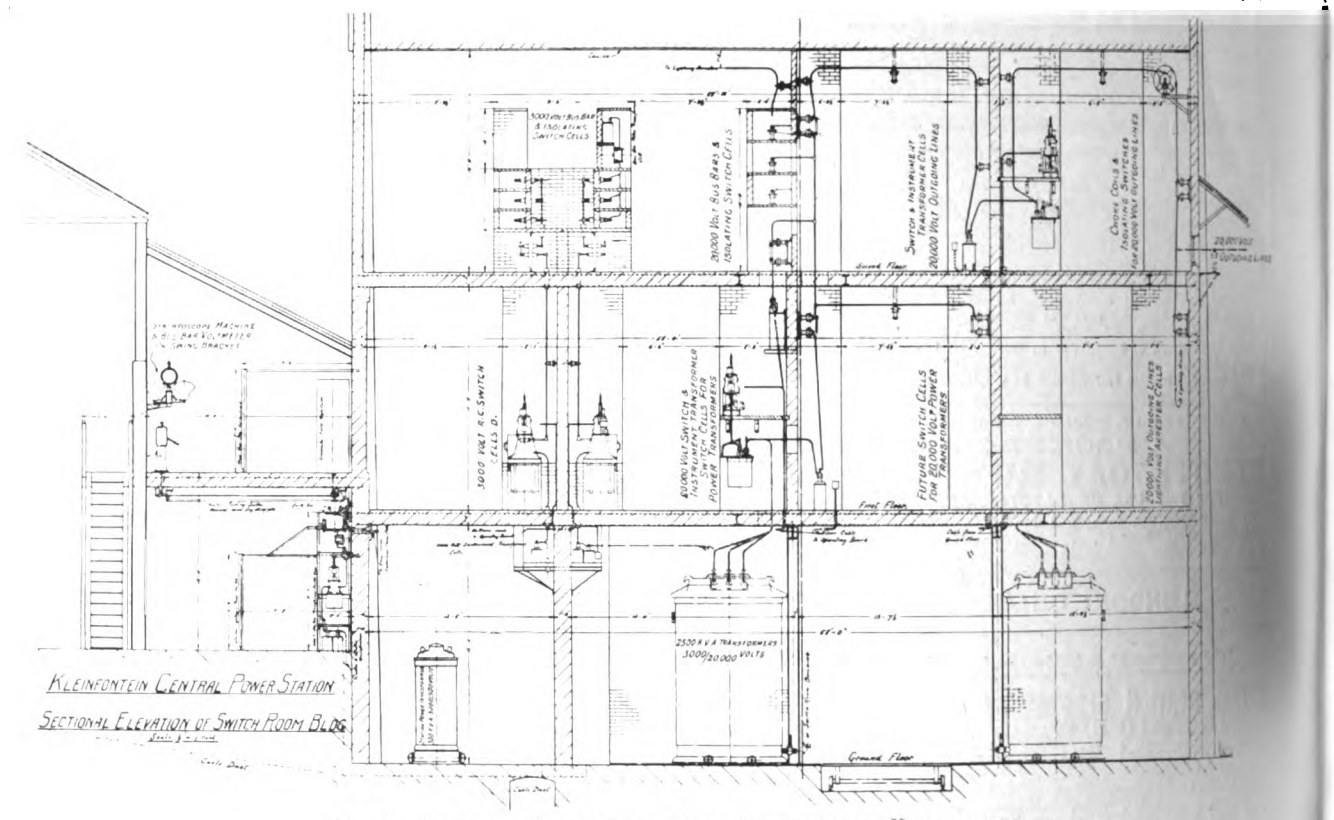

Fig. 1.—Sectional Elevation of Main Switchgear at Kleinfontein.

Digitized by Google

feeders. At the present only three generators are installed and these are rated at 3,000 kw. each. They are turbine-driven and generate current at 3,000 volts with a frequency of 50. The excitation is provided for by common exciter bars which are fed from motor-generators, and also by a battery of 66 cells having a capacity of 120 ampere hours. The present transformer installation consists of four step-up transformers, each having an output of 2,500 kw. These are wound mesh on the primary and star on the secondary side, and transform the current up from a pressure of 3,000 to 20,000 volts. The neutral point of the extra-high-tension system is not earthed whilst the neutral point of the high-tension system is directly earthed without the insertion of a resistance. Each generator has its neutral point brought out, and by means of a non-automatic hand-operated oil switch all these points can be connected to a common earthing bar. It is proposed at a future date to instal an automatic earthing arrangement by means of which it will be impossible to earth more than one generator neutral point at the same time.

FIG. 3.—AUXILIARY SWITCHBOARD.

A sectional elevation of the main board is given in Fig. 1. The switchgear consists of two main portions: the operating panels (Fig. 2) which are erected on a gallery across the whole width of the engine room, and the high-tension and extra-high-tension switchgear which is erected in a separate switch house; the auxiliary switchboard (Fig. 3) for the main station is placed underneath the gallery. From the operating panels in the engine room the high-tension and extra-high-tension switchgear in the switch house is electrically controlled. The high-tension and extra-high-tension apparatus are arranged in cells built up of brick and reinforced concrete. Each three-phase circuit on the 3,000-volt system is separated from its neighbour by a 4½ in. brick wall, whilst in the 20,000-volt switchgear not only the circuits but also the phases are separated from each other by similar walls. The 3,000-volt switchgear is erected on the low-tension side of the switch house, the various cells being arranged back to back on each side of a vertical 14 in. brick wall. Commencing from the ground floor, the three-core cables from the generators end in trifurcating boxes, fixed to the 14 in. brick wall. From these cable receivers the bare copper rod connections pass through horizontal concrete slabs into the current and potential transformer cells. The conductors pass thence through the second floor into the switch cells, and from the switches through the third floor into the isolating switch cubicles and 'bus bar compartments. The 'bus bars are divided from one another by horizontal concrete slabs and form a complete ring. Proceeding downwards from the 'bus bars on the other side of the vertical wall there are first the isolating switches on the third floor, the automatic oil switches on the second floor, and the current transformer cubicles on the first floor opposite the corresponding apparatus on the other side of the wall. The primary terminals of the 2,500 kw. transformers are connected by means of bare round copper rods to the terminals of the current transformers.

From the secondary (20,000-volt) terminals the connections pass through large holes in the second floor to the automatic-oil switches, thence through the vertical wall to the current transformers, and through the third floor into the 'bus bar compartment. The oil switches for controlling the outgoing feeders are all erected on the third floor in a separate set of

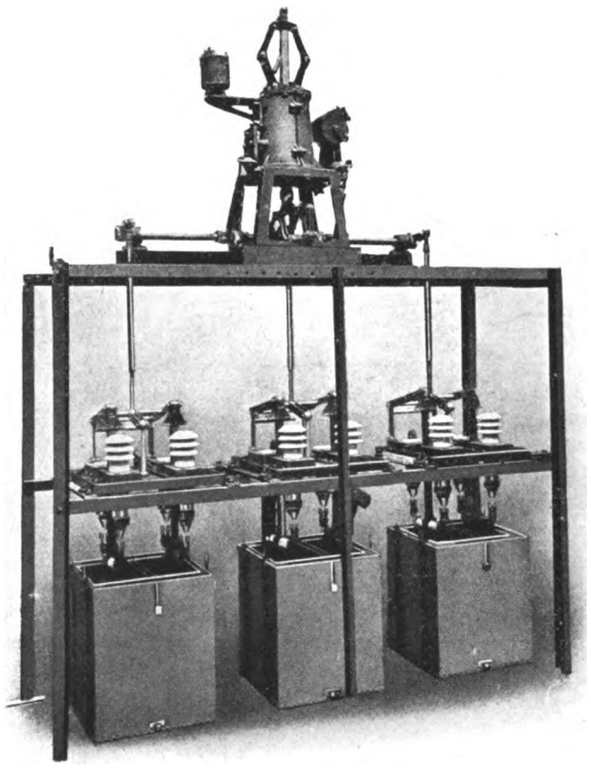

FIG. 4.—20,000-VOLT MAIN SWITCH.

cells. The conductors from the 'bus bars pass through isolating switches overhead fixed to the roof of the current transformer cells, from there through the auto-oil switches to the choking coils fixed against the main outside wall and then the conductors leave the building through isolating switches and suitable openings in the main wall. Proceeding downwards from where the lines enter the building, connections pass through the third floor into isolating switches and thence to the lightning arrester cells, all of which are erected on the second floor. The operating board as at present equipped consists on the low-tension side of four power transformer panels, three blank panels for future generators, three generator panels, one panel for automatic voltage regulation, two blank panels for future exciters, two exciter panels, one continuous-current motor generator panel, one group feeder panel, one pumping station panel, one 3,000-volt outgoing feeder panel and four outgoing overhead feeder panels. Each generator panel is equipped with three ammeters, one voltmeter, one indicating wattmeter, one power factor indicator, three reverse relays, one fool-proof controller for the reverse-current switch, two indicating lamps for this switch, one field ammeter, one field

Digitized by Google

voltmeter, one double-pole field switch, two fuses, and one three-phase unbalanced wattmeter. In front of each generator panel is an iron pedestal containing the handwheel of the field regulator and the handle of the neutral point oil switch referred to above. The motor-generator panels controlling the continuous-current side of two motor-generators contain: two automatic direct-current carbon circuit-breakers, two ammeters, two voltmeters, two double-pole quick-break knife switches, four fuses, two shunt regulators and one direct-current watthour meter. Each main transformer panel contains: three ammeters, one fool-proof Ferranti controller for operating the two main switches, viz., one primary and secondary switch at the same time or one after the other by means of plugs, one overload relay installed on the primary side and one Merz-Price relay for the protection of the transformer. Each outgoing 20,000-volt feeder panel contains: three ammeters, one fool-proof controller, one set of indicating lamps, one overload relay and one three-phase unbalanced load watthour meter. The group feeder panel and the pumping station panel, as well as the outgoing 3,00-volt feeder panel, contain exactly the same apparatus and instruments as the 20,000-volt feeder panels The two exciter panels each contain at the top: three alternating-current ammeters for the alternating-current side of the motor-generator, one overload relay, one fool-proof controller and one set of indicating lamps, one direct-current ammeter, one direct-current voltmeter, one handwheel for the liquid starters for starting the motor-generators from the direct-current side, one handwheel for the shunt regulator, one double-pole field switch two fuses, and one three-phase unbalanced watthour meter. Underneath the switchboard gallery in the engine room is erected the switchgear for controlling the power and lighting supply of the station itself. It consists of a high-tension switchboard containing three panels for the control of the power and lighting transformers situated immediately at the back behind the main wall and of a low-tension switchboard containing the apparatus for controlling the low-tension side of the transformers and the power and lighting distributors.

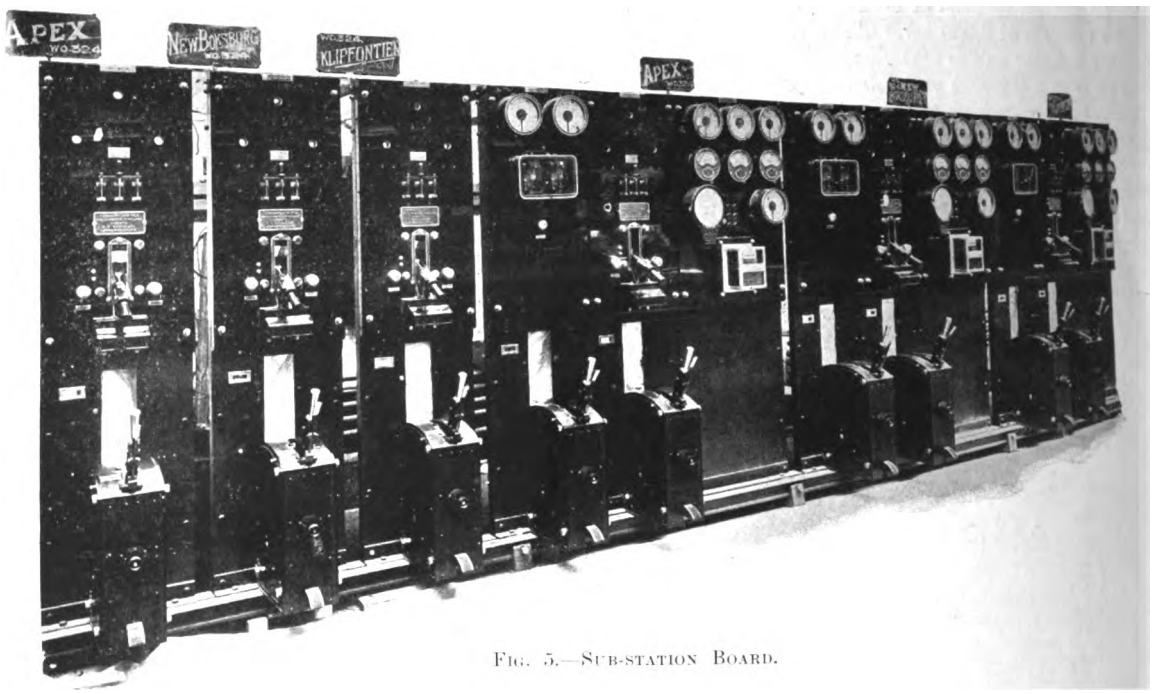

Fig. 5.—Sub-station Board.

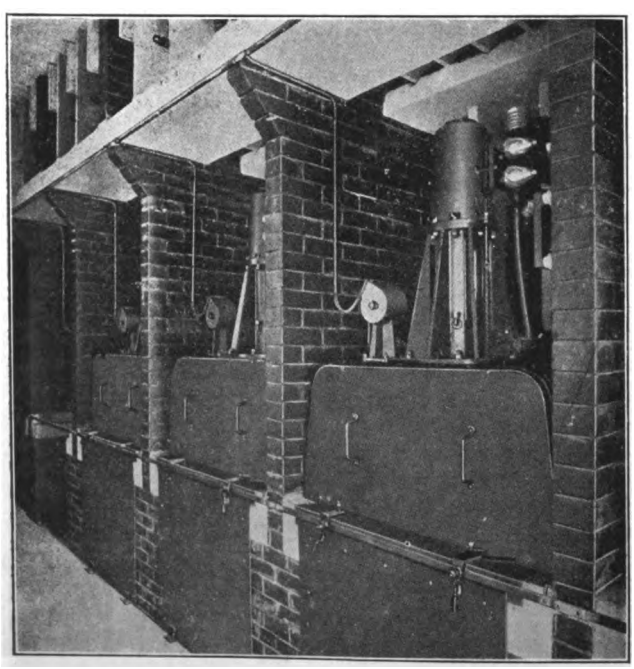

Fig. 6.—3,000-volt Main Switch.

The switchgear generally possesses all the automatic protective devices which are now considered to be up-to-date and efficient. The generators have been provided with reverse power relays only. The main transformers are protected by means of the discriminating Merz-Price system and with overload protection on the primary side only. The group feeders and outgoing extra-high-tension feeders are also provided with auto-time limit overload devices.

Having dealt with the general arrangement, it may be of interest to describe some of the apparatus in greater detail. The main switches naturally take first place. As already shortly indicated, all the main oil switches are electrically operated and are of the well-known Ferranti-Field design They are solenoid operated the co ilsbeing energised at 100 volts, by the battery referred to above. The 3,000-volt main switches are all of the same size as far as breaking capacity is concerned. They are of the largest size yet manufactured by Messrs. Ferranti, and are capable of breaking 30,000 kw. without the least difficulty. They only differ from one another as regards current-carrying capacity in order to suit the normal loads of the various circuits. As will be seen from the illustration (Fig. 6) each phase is interrupted in a separate tank, the total break per phase being 18 in. under oil. The 20,000-volt switches (Fig. 4) are of Messrs. Ferranti's standard 30,000 volt size. They are different from the 3,000-volt switches in that each phase has

a separate switch erected in a separate cubicle. On top of the switches and separated therefrom by a horizontal concrete slab is fixed the operating gear, consisting of a powerful solenoid which by a suitable arrangement of levers operates the three-single-phase switches at the same time. In each switch cubicle there is mounted against the wall a suitable terminal board to which are connected the ends of the steel armoured multi-core cable, thus forming the link between the fool-proof controller on the operating panel and the switch, the multi-core cable being connected to similar terminal boards at the back of the operating panels. The isolating switches are of Messrs. Ferranti's standard design and are very substantially built. As already indicated above, the 'bus bars are on the ring main system and suitable isolating switches are installed in the run of the 'bus bars in order completely to isolate not only a particular circuit but also that part of the 'bus bar to which that circuit has connected. The 3,000-volt 'bus bars have each a section of 3 sq. in. They are of the laminated type and are supported by substantial insulators cemented into the wall. The 20,000-volt insulators used throughout are of Messrs. Ferranti's standard 30,000-volt size, and are of the built-up type having two "petticoats."

All current and potential transformers are of the enclosed oil-cooled type, and altogether the whole switchgear has been designed to withstand the South African climate. The metal framework of the operating board and that of the high-tension and extra-high-tension compartments, as well as the cases of all transformers and switches, the cable receivers, and the secondaries of all instrument transformers, are effectively earthed by means of bare copper strips which are connected to the main earthing bar of the station. The switchgear in the five sub-stations (Fig. 5) is of similar design to that of the main station, with the exception that all the oil switches are of the mechanically remote controlled type. The whole of the switchgear in the main station and sub-stations were designed and built by Messrs. Ferranti in their Hollinwood works, and it goes without saying that the work turned out by them is throughout of first-class finish and workmanship.

G.E.C. Electric Haulage Gear.

The great development of electrically driven haulage gear in mines cannot be better exemplified than by referring to some typical installations which have been supplied by the General Electric Co. We give below details of two such installations which they have recently carried out.

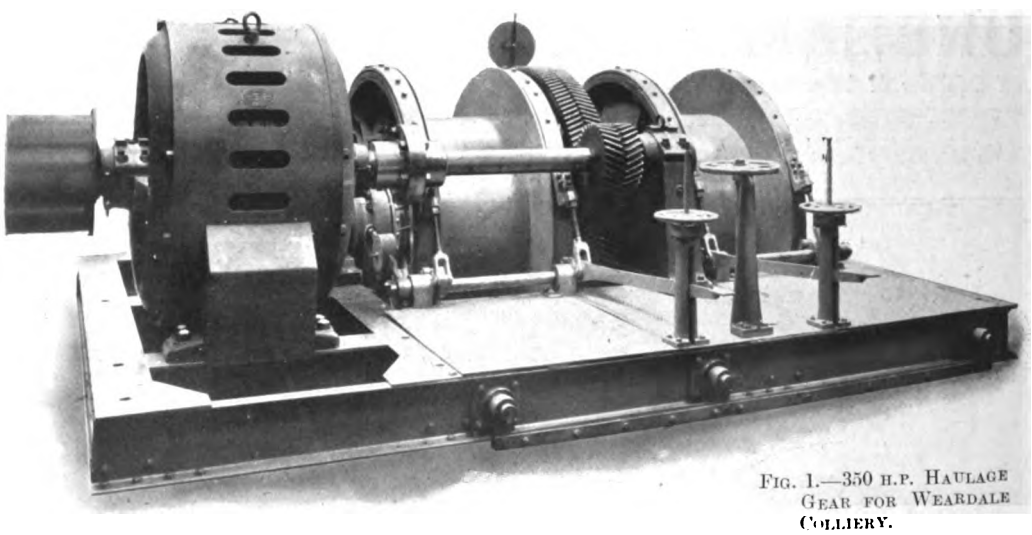

FIG. 1.—350 H.P. HAULAGE GEAR FOR WEARDALE COLLIERY.

Fig. 3 shows the 20 H.P. main and tail haulage gear supplied by them to the Thornbury Colliery. This gear is driven by a 20 H.P. three-phase slip-ring motor running at 760 revs. per min. and working on a 450 to 500 volts circuit with a frequency of 40. The gearing is proportioned to give a rope speed of 6 miles per hour. The motor has gas-tight slip-rings and is supplied with an oil immersed controller for regulating the speed. Fig. 2 represents a 7 H.P. squirrel-cage motor working on a 440-volt circuit with a frequency of 40. It runs at 1,160 revs. per min., and drives through gearing a three-throw portable ram pump, which is capable of delivering 100 gallons per minute against a head of 100 ft. The rams are 5 in. in diameter of the trunk type, and have a 6 in. stroke. The motor is of the squirrel-cage type, and is started by means of an oil-immersed auto-transformer. Fig. 1 shows the 350 H.P. haulage gear supplied to the Weardale Coal Company. The motor is 350 H.P., and works on a 3,000-volt 40-frequency circuit. It runs at 335 revs. per min., and its controller is capable of starting it against full-load torque once in every 7 minutes, and also of regulating the speed down to one-seventh of the full-load speed for one hour. The gearing is so proportioned that the speed of the ropes is 14 miles per hour, and the drums are capable of accommodating 2 miles of rope.

Controllers and Resistances in Mines.

BY EDMUND GARSIDE.
(Of Engineering Instruments, Ltd.)

In view of the Report of the Departmental Committee and their suggestions for the modification of the existing Special Rules for the use of electricity in mines, it will be necessary for designers to consider the question of resistances to comply with the rules.

In the application of motor driving in coal mines the most difficult conditions which require fulfilling in regard to resistance design are for resistances for use with controllers operating large motors driving main and tail haulage gears. In this class of drive, in many cases, it is necessary to run the motor dead slow with very light loads, and also at all speeds from 15 per cent. of full speed up to full speed, with varying conditions of load, from practically no load to full load. Considerable difficulty has been experienced in meeting these conditions owing to the space required for the resistances and their high cost. The type of resistance usually used is of the cast-iron grid type in ventilated cases, this having been the standard type of resistance for controller work for industrial purposes.

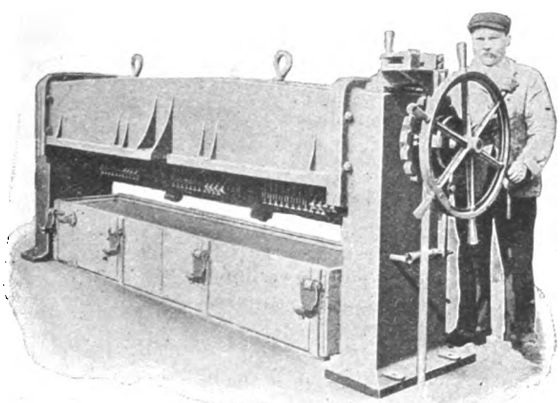

FIG. 1.—MINING CONTROLLER.

Owing to the above difficulties the tendency during the past few years has been in favour of using a liquid controller, the controller and resistances being a self-contained piece of apparatus. This type of controller has been used largely for haulage work, but owing to the fact that liquid has to be employed it has several disadvantages which do not exist with properly designed, controllers with metallic resistances. In the later designs of liquid controllers for large motors where a large amount of control is required, and consequently where a large amount of energy has to be dissipated in the resistances, water-cooling circulating pipes have been employed to cool the liquid of the controller, water being pumped through the circulating pipes by means of a small centrifugal pump fixed on the haulage bed plate and driven from the haulage gear.

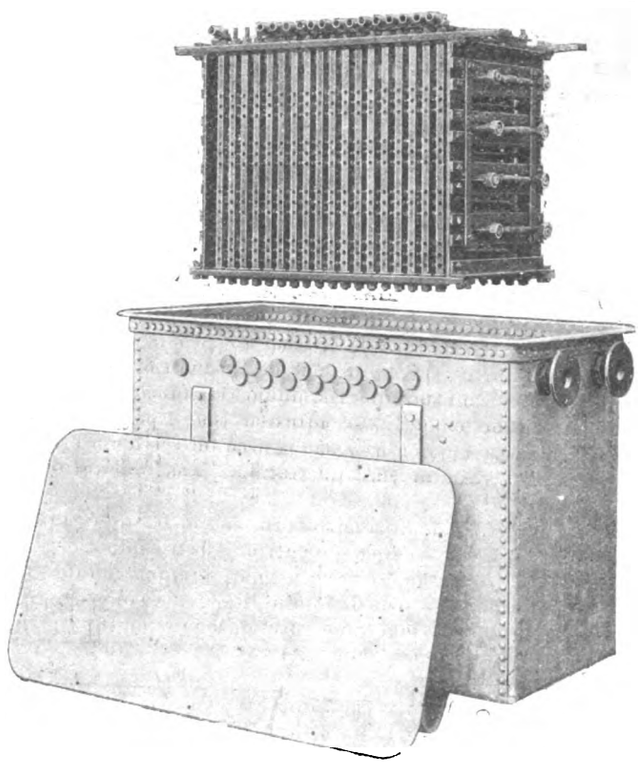

FIG. 2.—OIL TANK, WITH RESISTANCE.

This method of dissipating the energy expended in the resistances in heat has proved very satisfactory owing to the fact that when the haulage gear is running light, and at a high speed, a greater quantity of water is circulated through the tubes, and thus cools the resistances between the runs. The amount of active material, therefore, in the resistances is

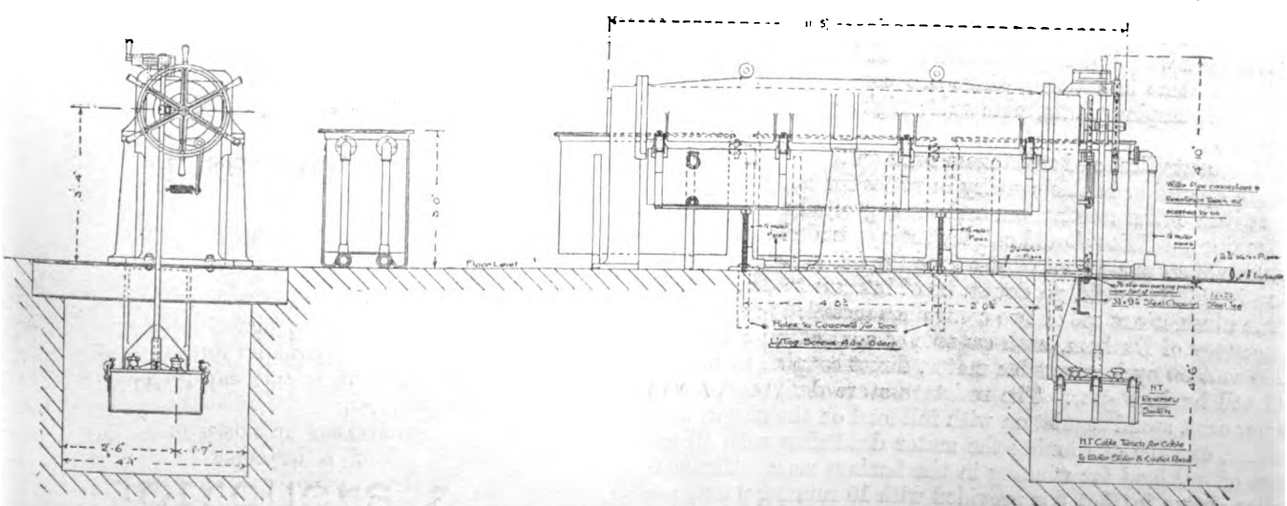

FIG. 3.—ELEVATION OF HAULAGE CONTROLLER GEAR.

Digitized by Google

reduced to a minimum, with a resulting saving in space occupied and also in cost.

The liquid controller, however, has serious disadvantages owing to the presence of the liquid, making it extremely difficult to obtain efficient insulation. Also, there is considerable loss of liquid by evaporation at temperatures which exist in mines, and also loss due to steam being generated in the controller when the liquid is called upon to dissipate any considerable amount of energy. In situations where resistances have to be totally enclosed it would, therefore, appear that the employment of liquid controllers offers difficulties which will be by no means easy of solution.

In the liquid type of controller it is usual to arrange for the dipper plates never to break circuit; there is, therefore, a danger, if periodical inspection is not maintained, as the loss of liquid by evaporation will so lower the level as to cause the dipper plates to open circuit when the controller is in the position where all the resistance should be in circuit.

It would appear, therefore, that the type of controller and resistances for the control of motors in mines to comply with the suggested modifications of the Special Rules should be so designed that the controller contacts and the resistances be totally immersed in oil, the resistances being of the metallic type contained in totally enclosed oil-filled tanks. Water-cooling circulating pipes should then be provided in the resistance tanks having sufficient area to keep the oil at a normal temperature when the resistances are dissipating the maximum amount of energy required. The circulating pipes should be fed with water by a small centrifugal pump driven by the haulage gear. The amount of water required will, of course,

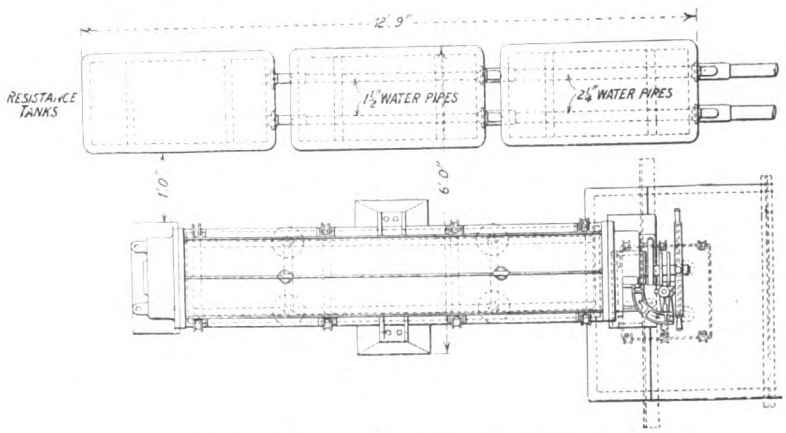

FIG. 4.—PLAN OF HAULAGE CONTROLLER GEAR.

depend upon the energy to be dissipated, and in some cases a water tank would be required with a ball tap to maintain the level. In some situations, where the controllers are in the vicinity of pumping plants, mine water might be used for cooling purposes.

A few controllers and resistances built on this principle have been in operation in this country in mines for some years and have given entire satisfaction, and the suggested modifications to the Special Rules should call for their extended use. As an instance of an equipment of this type the following particulars of an installation will, no doubt, be of interest to designers.

The illustrations are of two controllers installed in a mine in the county of Durham, each capable of controlling a 400 H.P. 2,750 volt 50 cycle reversible motor, direct coupled to a main and tail haulage gear. The resistances are designed to give 50 per cent. speed regulation with full load on the motor, and, further, capable of running the motor dead slow with 10 per cent. of full load for winding in the haulage rope. The controller shown in Fig. 1 is provided with 15 running points per phase, all the contacts being oil immersed, each breaking point being effected by a quick make-and-break switch, the speed of the make-and-break being out of the control of the operator, the length of break being 4½ in. The controller is connected to the rotor resistances, the rotor being wound for 500 volts. The high-tension reversing switch is mounted in the foundations below the floor level, and is interlocked with the controller hand wheel. All the high-tension switching arrangements and cables are, therefore, below the floor level in the cable trenches.

The resistances shown in Fig. 2 are of the unit type divided into three sets, one tank with its resistances being provided for each phase. The resistances are entirely immersed in oil, each tank containing four sets of copper circulating coil pipes connected in parallel with the main water supply provided by the centrifugal pump on the haulage bedplate. The general arrangement of the lay-out of the controller, together with the resistances, is shown in elevation on Fig. 3 and in plan on Fig. 4.

With the above arrangement of the resistances, perfect cooling can be maintained, and there is no danger of arcing in the event of the resistance burning out, as any arc so formed is immediately damped by the oil. This type of apparatus, while being slightly more costly in the first instance, provides every security to the mine, renders open arcing an impossibility and meets the requirements of the Special Rules.

Progress in Mining Switchgear.

One of the most noticeable features in recent development of mining switchgear has been the total abolition of the use of slate or marble for supporting the various apparatus. In a

FIG. 1.—INVERTED TYPE MINING PILLAR.

modern colliery such material is only to be found in the generating station, where appearance may sometimes warrant

FIG. 2.—100 AMPERE LOW VOLTAGE UNIT FOR UNDERGROUND WORK.

its inclusion. The present-day form of iron-clad switchgear had its rise in the now old-fashioned inverted type pillar (*see* Fig. 1). As will be seen from the illustration these were

Digitized by Google

extremely clumsy in their construction when compared with modern apparatus for similar purposes, and, moreover, the apparatus contained within was so cramped as to render access to details for purposes of adjustment a matter of some difficulty. Their principal advantage over the still older forms of mining switchgear was that they were so strongly constructed that they could well withstand the extremely rough usage which was to be expected, and they were moreover arranged with interlocking devices so as to prevent the operation of the isolating switch before the oil switch circuit was opened, and also to prevent the door being opened until both these switches were previously opened. As a direct descendant of this in-

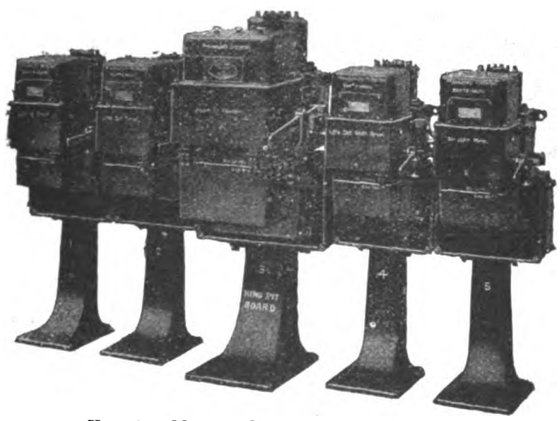

FIG. 3.—MINING DISTRIBUTION BOARD.

verted type of pillar there came the sheet iron or wardrobe construction which, in various forms, has now been taken up by the majority of the leading manufacturers in this country and abroad. In this class of apparatus the chief object has been not so much to secure economy in space, but rather to ensure that all apparatus is so arranged as to be fool-proof in operation, while it is spaced within the sheet-iron cubicles as widely apart as would have been the case had the ordinary form of cellular construction been adopted. This class of gear is primarily

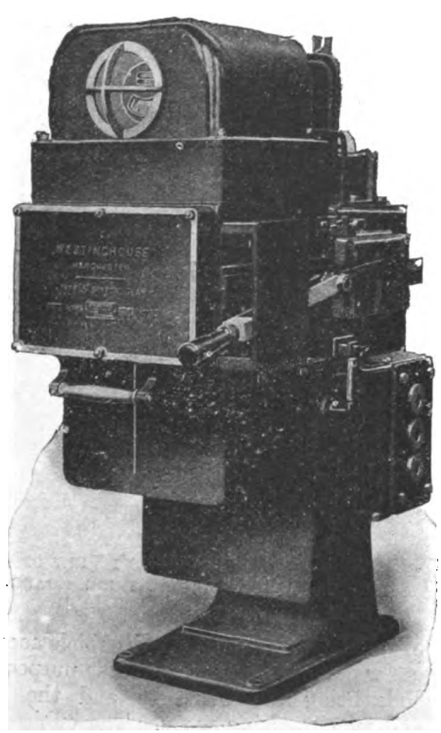

FIG. 4.—6,600-VOLT MINING PILLAR.

intended for sub-station service where the head room occupied is not an important item.

For use underground, the British Westinghouse Co. have, within the last few years, developed a new form of apparatus, which they term their type "S" switchgear. In its simplest and original form it is shown in Fig. 2, which illustrates a 100-ampere low-voltage unit. The most noticeable feature of this type of apparatus is its extreme flexibility, the completed units being built up of separate interchangeable portions, most of which are so ingeniously designed as to be usable for several different purposes.

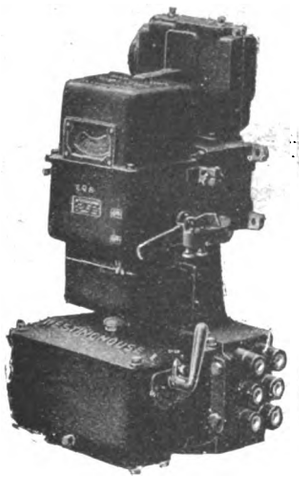

FIG. 5.—ANOTHER TYPE OF MINING PANEL.

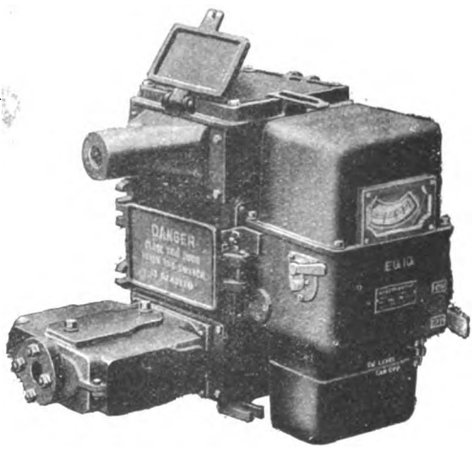

FIG. 6.—STANDARD GATE END BOX WITH ANDERSON BOYES TRAILING CABLE PLUG.

Thus, in Fig. 3 is shown a complete distribution switchboard arranged for a 200-ampere incoming circuit, and four outgoing circuits of 100 amperes. The total height of this switchboard need not exceed 44 in.; it will thus be seen that this apparatus is suited for use in very shallow headings indeed.

Further forms of this apparatus are shown in Fig. 5, which

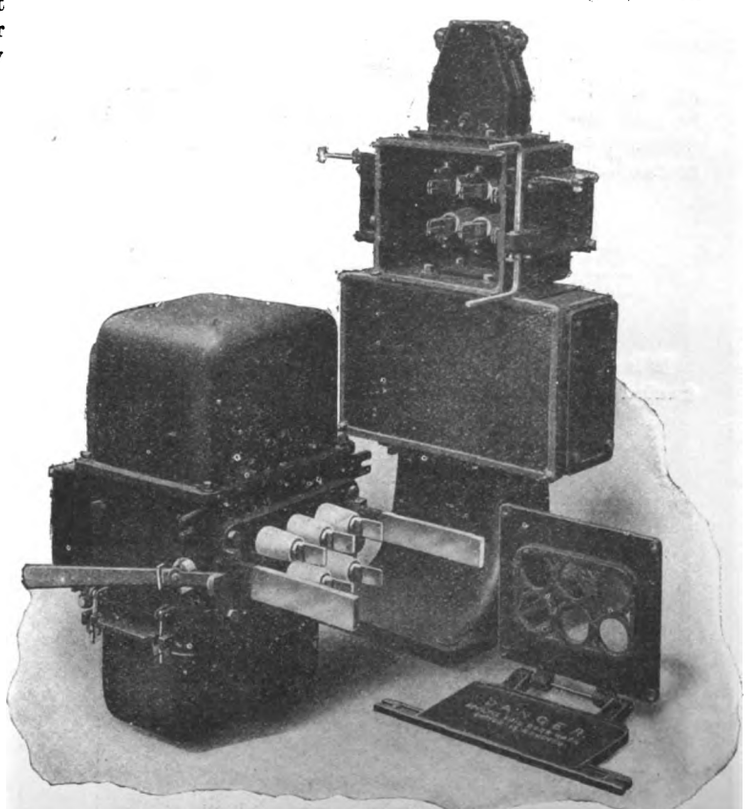

FIG. 7.—3,300-VOLT PILLAR SHOWING PARTS.

illustrates a low-voltage switch working in conjunction with an oil-immersed star delta starter, and also Fig. 6 which shows the standard gate end box complete with an Anderson Boyes trailing cable plug. In this case the total height of the appa-

Digitized by Google

ratus is 20 in. This apparatus is also built for use on higher voltages, Fig. 4 showing the arrangement of the 6,600-volt pillar, while Fig. 7 shows a 3,300-volt pillar. This latter illustration also serves very effectively to illustrate the arrangement of isolating plugs which are so important a feature of the "S" type switchgear. The apparatus is so designed that access cannot be obtained to any of the current-carrying parts of the switch until the switch is actually isolated from the line, and also from the outgoing cables. The interlocking devices included are complete in every particular, and, it is claimed, render it an absolute impossibility for the operator to receive a shock.

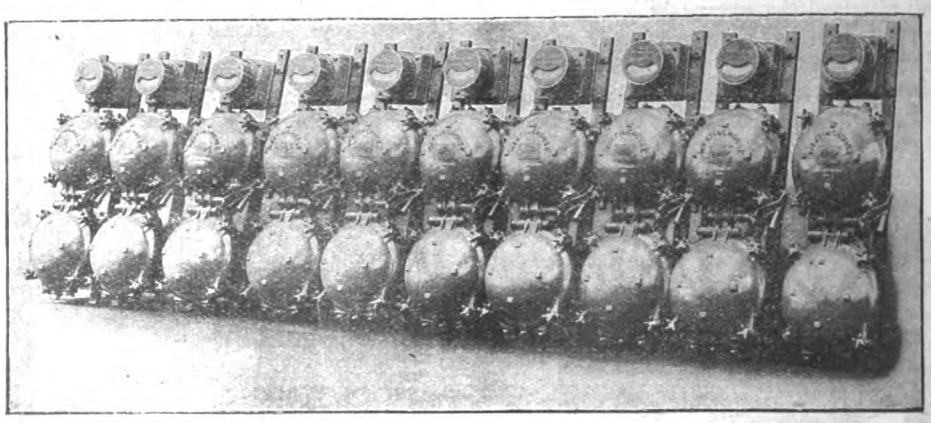

FIG. 8.—WESTINGHOUSE DIRECT-CURRENT FLAME PROOF SWITCH UNITS.

For direct current service, the Westinghouse Company still employ their well-known flame-proof switch units which are illustrated by Fig. 8. The principle on which these units is constructed is to build the fixed and hinged portions of each switch or fuse unit in such a manner that a circular V-shaped tongue on the one fits into a corresponding circular V-shaped groove in the other. By this means any flame which might be caused by an arc within the switch case cannot be transmitted to the atmosphere without, as it would first of all have to pass between closely fitting metal surfaces for a long distance, and these would effectually cool the gases so as to render them harmless.

An Up-to-date Mining Switchboard.

It is obvious that electric installations in mines have to be treated from an altogether different point of view than ordinary surface installations, as a breakdown in the motive power of a mine will probably have disastrous consequences. Therefore every precaution must be taken to make the installation safe regardless of expense.

Hitherto one of the most likely places for a fault to occur has been the switchboard, with its numerous connections, cables and other apparatus. The board shown in the illustrations, which has been designed and manufactured by the General Electric Co. for colliery work, is a very good example of an up-to-date mining switchboard. The term "switchboard" is rather misplaced when applied to an installation of this description, which has, as will be seen, very little in common with the old time-honoured marble and slate boards. As a matter of fact no marble or slate is used whatever, steel plates having taken their place.

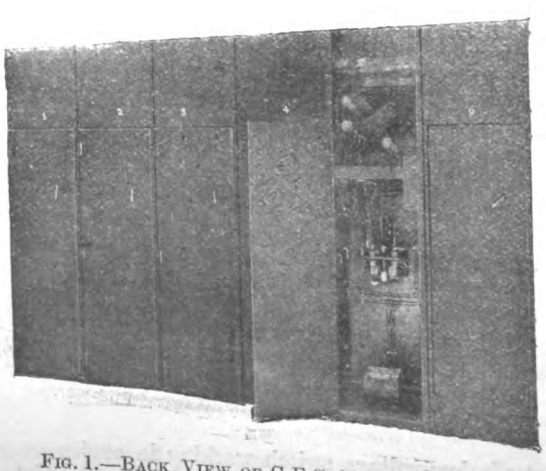

FIG. 1.—BACK VIEW OF G.E.C. MINING BOARD.

The "board" consists of six cubicles formed by steel plates bolted to an angle iron framework. Each cubicle accommodates one set of gear which serves one particular purpose, the only connecting link being the 'bus bars and the low-tension instrument and synchronising wires. The cubicles from the right to the left of the observer, looking at the front of the board, deal with the following duties :—

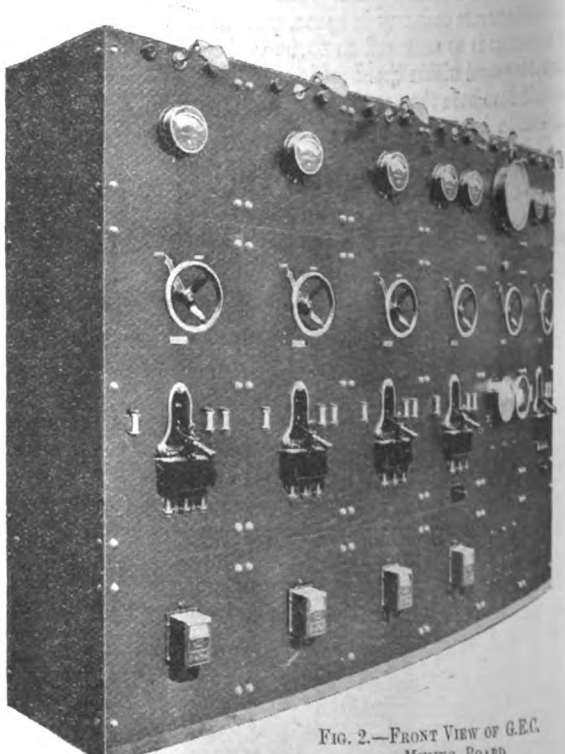

FIG. 2.—FRONT VIEW OF G.E.C. MINING BOARD.

No. 1 : One 750 kw. 3,000-volt three-phase turbo-alternator, for which is provided one maximum release oil switch, three series transformers, an ammeter, one potential transformer, a voltmeter, synchronising plug, and high-tension disconnecting links. No 2: High-tension disconnecting links, three-phase potential transformer, synchroscope, hot

Digitized by Google

age indicator, and indicating wattmeter for the alternator on No. 3. No. 3: One interconnecting feeder. The gear provided is the same as on No. 1, with the addition of a watt-hour meter in place of the indicating wattmeter, Nos. 4, 5 and 6 are for three feeders, two of 750 kw. and one of 150 kw. capacity. The gear provided for each is a three-pole disconnecting link, three series transformers, one three-pole maximum release high-tension oil switch, an ammeter and a watt-hour meter.

All the oil switch trip coils are provided with time limit fuses across their terminals. These fuses are of the porcelain handle type, and can be seen in the front view of the "board" (Fig. 2).

The 'bus bars are carried in three horizontal chambers running along the whole length of the top of the "board." The chambers are formed by steel plates on the top and sides, and they are open below. Directly under the 'bus bars in each cubicle are mounted the disconnecting links on the side plates which separate two adjacent cubicles. The access doors at the back of the cubicles only reach just below the lower or hinged contacts of the isolating links while the upper contacts, which are connected to the 'bus bars and which form the only live metal parts in the cubicle when the disconnecting links are switched out, are covered up by steel plates bolted to the angle irons forming the frame. This can be plainly seen by referring to the back view (Fig. 1). The three disconnecting links of each cubicle are connected together into a three-pole switch in the manner shown in Fig. 3, which illustration shows a cubicle

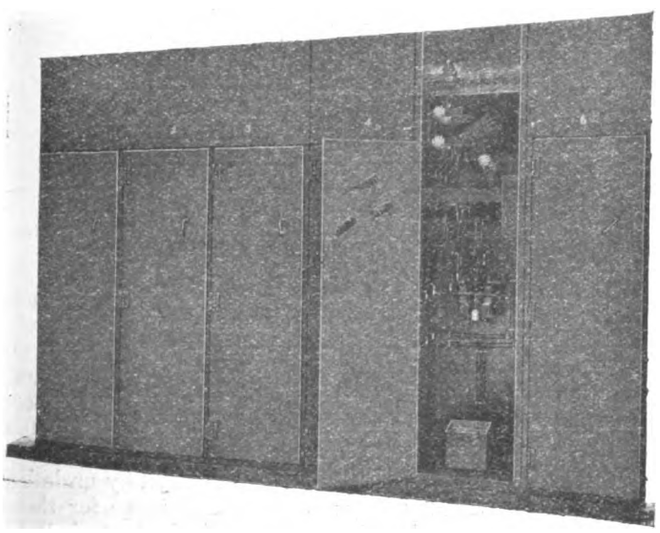

FIG. 3.

with a number of steel plates removed. It will be seen that no coupling bar in the ordinary sense is used, and that each individual link is attached to a ribbed vitreous porcelain insulator which is in turn attached to a crank on the common operating shaft.

This method, it is claimed, ensures perfect insulation, and at the same time does away with the necessity of cutting slots in the partitions between the links to make room for the coupling bar. The operating shaft cubicle in front (*see* Fig. 2) is interlocked with the door in the rear in such a way that it is impossible to open the door as long as the disconnecting links are switched in, and to close the disconnecting links as long as the door is open. The oil switches are mounted on the front steel plate of the cubicle under the operating shaft of the isolating links, and are interlocked with the latter in such a way that they can only be closed if the isolating links are switched in, while, if they are closed, they lock the isolating links. This system of interlocking makes the board quite fool-proof, for it is impossible to break the circuit with the disconnecting links, as they are locked as long as the oil switch is closed, and it is also impossible to open the doors of the cubicles as long as the disconnecting links are switched in. Furthermore it is impossible to switch in the disconnecting links as long as the door is open.

Some New Oil-break Switches for Mining Work.

The ever-increasing application of electricity to mining, and the need for safety and reliability—more especially the necessity of complying with the requirements specified by the recent

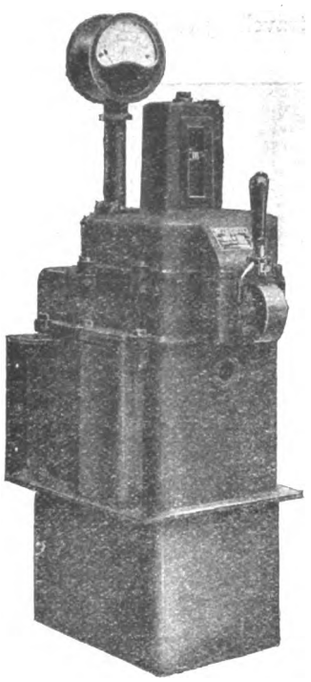

FIG. 1.—TYPICAL "UNION" OIL SWITCH FOR MINING WORK.

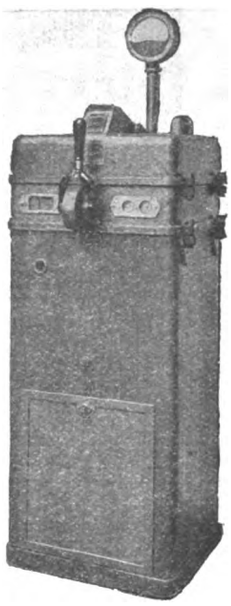

FIG. 2.—H.T. OIL BREAK SWITCH.

Royal Commission—have resulted in improvements in, and new types of, switchgear to adequately control the supply of electrical energy.

Each application of electrical power to a new industry calls

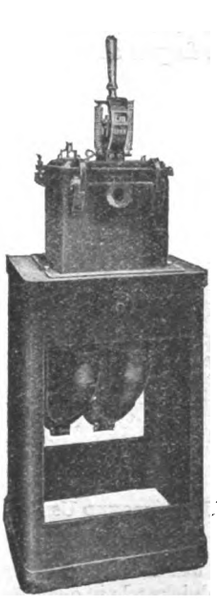

FIG. 3.—METHOD OF ATTACHING CABLE JUNCTION BOX TO OIL CONTAINER.

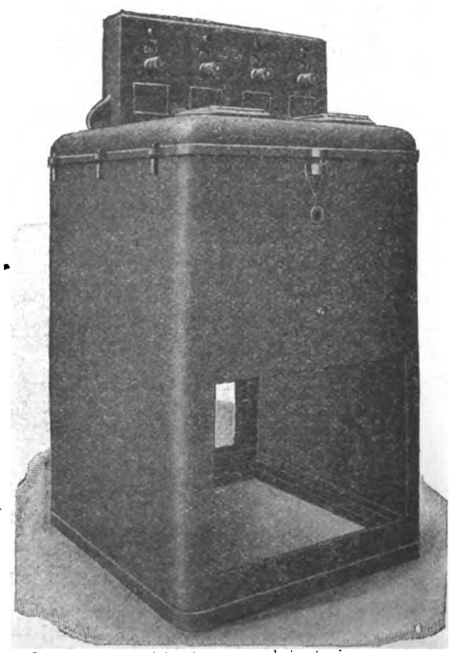

FIG. 4.—OIL BREAK ISOLATING SWITCH BOX WITH CABLE AND SEALING BOXES.

for special designs of machines and switchgear; and it is essential, for mining purposes, that the switchgear shall be solid in design, capable of use without damage by unskilled labour

Digitized by Google

and flame-proof. It is now some seven years since the Union Electric Co. commenced the manufacture of special types of oil-break switchgear having the above characteristics and suitable for severe working conditions; and they adopted the then exceptional feature of placing all circuit terminals in the base of the oil-container. A typical switch of this pattern is shown in Fig. 1. It is a triple-pole, oil-break, flame-proof switch, which is generally used in the Union switchboards of the carriage type. In these cases the switch units are mounted in cast-iron frames with wheels travelling on cast-iron canti-

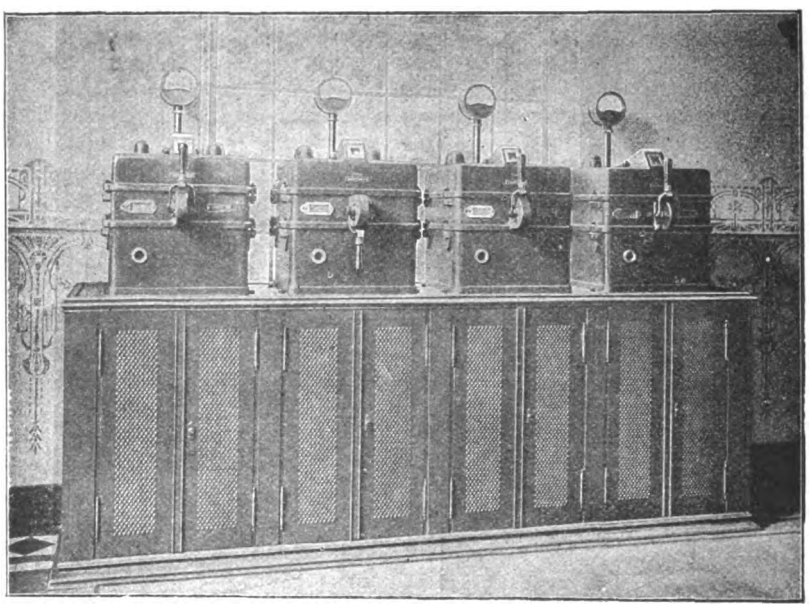

FIG. 5.—"UNION" MINING FEEDER BOARD.

lever brackets, behind which are the chambers for 'bus bars and isolating links. This system embodies the Union Electric Co.'s latest improvements for securing absolute safety when used in underground positions. By the special system of electrical and mechanical interlocking, it is said to be impossible under any conditions for live parts to be exposed. This result is obtained as follows:—Connection between the switch unit and the 'bus bars is made through switch-fingers at the back

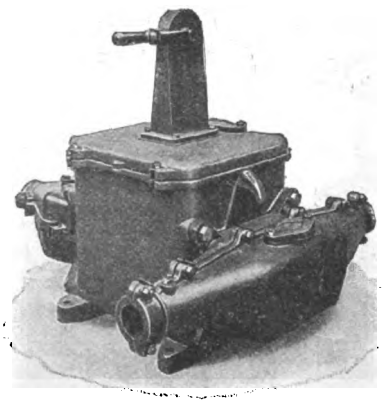

FIG. 6.—SECTION INSULATOR FOR UNDERGROUND USE.

of the unit, and at the front of the 'bus bar chamber. Connection to the no-volt trip-coil of the switch is made in a similar manner. The lever for withdrawing the switch carriage is so arranged that the no-volt trip contacts are disconnected by the slightest movement towards the "out" position; while, conversely, the no-volt trip contacts are closed last thing.

Supposing the switch to be "in"; any attempt to break circuit by the isolating link will first break the no-volt release circuit, causing the oil switch to trip out automatically. On the other hand, if the carriage is "out" the switch cannot be closed, as it will be instantly tripped by the no-volt release, this effect being maintained until the carriage is right home and contact is established with the 'bus bars. If the carriage should have to be withdrawn for any purpose, the opening in the 'bus bar chamber is closed by a sliding panel, and secured with a padlock; enabling the rest of the board to be used with entire safety.

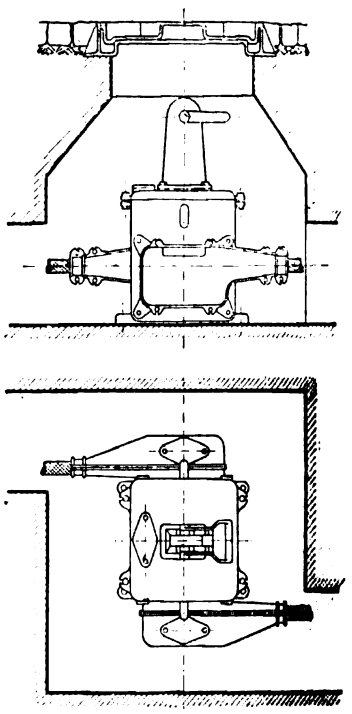

FIG. 7.—DIAGRAM OF SECTION INSULATOR FOR UNDERGROUND USE.

The overload coils are in the high-tension circuit and oil-immersed, securing better insulation and thus ensuring freedom from breakdown; owing to the direct operation there is, it is claimed, less complication than in the case of transformer-operated overload trips. The use of undertype circuit connections gives every facility for compact assembly of the switch units.

A switch system of this type is easily handled by unskilled operators with perfect safety; a great advantage for those power users who require that the electrical plant shall be controlled by unskilled workmen.

Figs. 2 and 5 show switches similar in design to the previous one, but suitable for higher pressures and larger currents. We illustrate in Fig. 5 a feeder board composed of these units. In special cases the overload trips can be supplied to secure a definite time-lag irrespective of the value of the overload current, so that it is possible to ensure that the switches shall be released in a definite order. In this type of switch design the cable junction-box may be attached directly to the oil-container, as shown in Fig. 3. This form of construction has been very largely adopted in gassy mines.

Fig. 4 illustrates an oil-break isolating switch-box with cable and sealing boxes. A number of isolating switches are assembled, with the requisite 'bus bars, in a large oil tank. For each set, cable-end sealing boxes are provided. The switches are operated by a loose key, and are fitted with an indicating device showing the "in" and "out" positions. The principal advantages of this arrangement are that the distributing gear occupies a very small space, while, owing to the complete enclosure of live parts, the apparatus can be used in gassy positions.

Figs. 6 and 7 show a section isolator for underground use with cable-end sealing boxes attached. This consists of a triple-pole oil-break sectionalising switch, mounted in a cast-iron sealing chamber. In use it is sunk in the cable trench, the cover and operating handle being accessible through a manhole.

Westinghouse Liquid Control Gear for use in Mines.

There exists at the present time a strong objection on the part of many engineers to liquid control apparatus. This objection is probably due to the fact that this type of gear can be manufactured for a very much lower price than metallic apparatus, and consequently the market has been flooded with cheap liquid starters and controllers which make no pretence at liberal rating in their design. As a result, liquid control apparatus has come to be regarded as representing the cheapest possible practice, a condition obtained at the expense of quality.

Liquid control gear, notwithstanding, possesses many advantages over metallic apparatus while its disadvantages practically disappear if the design is suitable. The most general objection raised is the "messy" nature of the resistance element, which gets spilt and boils, the steam condensing on the insulation and possibly breaking it down. A little consideration, however, will show that the resistance solution is no worse as regards spilling than the oil in oil immersed apparatus, which it is absolutely necessary to use in many cases for colliery or high-tension work. With regard to the latter objection it should be remembered that no boiling and very little steaming should occur when gear is properly rated for the work it has to do. It may be assumed, therefore, that if boiling or steaming does occur that the gear is too small.

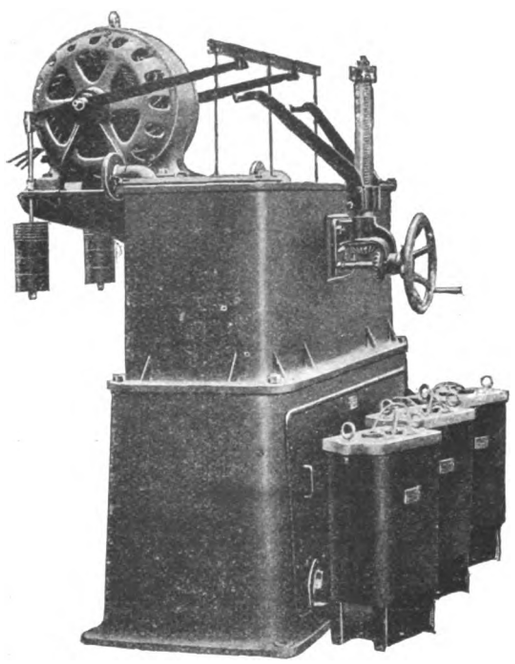

FIG. 1.—REVERSING LIQUID CONTROLLER FOR 1,500 H.P. MOTORS.

The British Westinghouse Co. have kept the above objections in view when designing their present line of liquid controllers, and although their apparatus is in general no cheaper than their metallic control gear, they claim that when used on the specified ratings the trouble of excessive steaming or boiling of the resistance liquid is wholly absent. Further, this class of apparatus gives uniform speed acceleration without jumps, while the speed adjustment is as wide as can be desired. As regards repairs, these are small, and can be effected on the site, while, owing to the simplicity of the contacts and connections, any work that has to be done on them is absolutely straightforward. Also with a liquid controller the resistance of the liquid can be altered simply by strengthening or weakening the solution. Thus any adjustments that may become necessary can be made on the site without trouble.

We describe herewith one or two patterns of Westinghouse liquid control apparatus. We may first mention a reversible haulage motor liquid controller with handwheel operating gear. The design of this apparatus is such that the rotor circuit is never broken, all the circuit breaking being done on the stator by oil immersed dust-proof reversing switches. All parts of the controller are entirely enclosed, and one operating handwheel performs all operations of reversing and bringing up to speed. Ten turns of the hand wheel are sufficient to move the controller from the "off" to full "on" position in either direction, thus enabling the operator to start or stop quickly. Cooling water is circulated through pipes immersed in the resistance liquid. Fig. 1 shows a reversing liquid controller for use with large winding gear motors, and in cases where exceptional speed variations with widely varying loads are likely to be met with. The particular controller illustrated is suitable for use with a 1,500 H.P. winding engine motor. The controller is of the sluice gate type, that is, it consists of two tanks through which the resistance liquid is kept in continuous circulation by a small motor-driven pump. The three electrodes connected to the slip-rings of the motor are in the upper tank, and the level of the resistance liquid in this is raised or lowered by the operator raising or lowering the sluice gate which is worked through rods and links from a lever or handwheel on the driver's platform. The stator reversing switches are also operated from the same lever. The operating lever is not shown in the illustration, the two handwheels shown at the left hand side being one for the valve in the delivery pipe for the circulating pump, and the lowering gear for the oil tanks and the reversing switches. It will be noted that with this arrangement of controller the maximum speed of acceleration is entirely out of the driver's hands, and is regulated by the rate of flow of the liquid into the upper tank. This can be adjusted to suit conditions by the valve mentioned above, which can be set on site and then locked. The whole of the cooling coils for the resistance liquid are arranged in the lower of the two tanks.

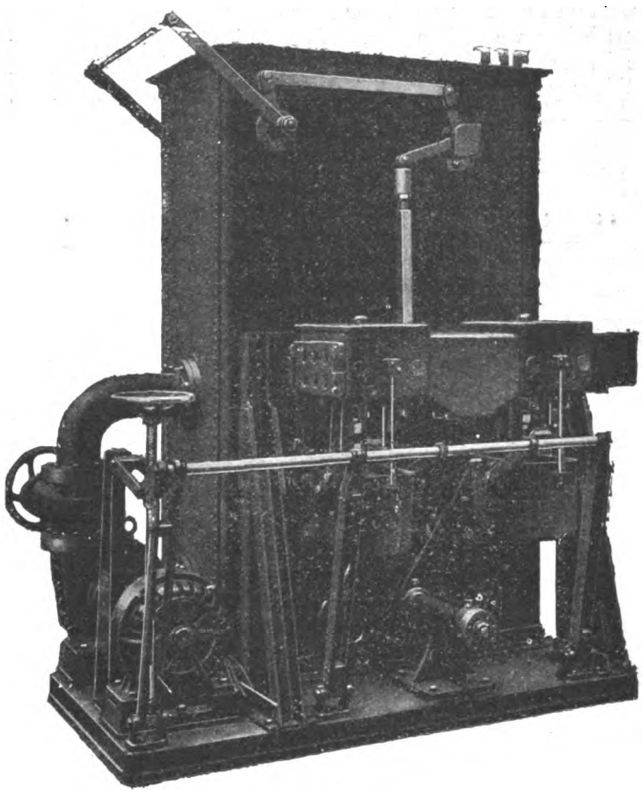

FIG. 2.—AUTOMATIC SLIP REGULATOR FOR WINDING MOTORS.

With regard to the stator reversing switches which are used with all these controllers, they are of the oil break type and are enclosed in dust-proof cases. Owing to the frequent and heavy service ordinary oil switches are not suitable, and those used have been specially designed for the controllers. They are of the strongest possible type to withstand the very heavy

Digitized by Google

service. The contacts are of the copper butt pattern, and are supplemented by laminated copper brushes where very heavy currents are likely to be employed. The final break is always taken on the copper butts which are easily and cheaply renewable. As mentioned above, the switches are operated from the same lever or handwheel as the rotor electrodes or sluice gate, and are fully interlocked.

Fig. 2 shows an automatic slip regulator for use with winding or rolling mill motors where some form of load equalising is in use. The apparatus consists of a liquid resistance connected in the rotor circuit of the motor, and a small auxiliary motor, or "motor magnet" as it is called, for cutting this resistance in and out of circuit. The motor magnet is supplied from transformers in the stator circuit of the main motor, these transformers being shown in the illustration. The apparatus is employed in cases where a flywheel is used on the main motor shaft. The motor magnet is so adjusted that when the load exceeds a predetermined value the liquid resistance is inserted in the rotor circuit by the motor magnet raising the electrodes. Thus the slip of the motor is increased and the excess load is thrown on to the flywheel. On the other hand, when the load drops below a certain value, resistance is cut out of the rotor circuit, the motor speeds up, and energy is stored in the flywheel. In this way the load on the line can be kept practically constant, all fluctuations being taken by the flywheel.

"Vickers" Oil-immersed Controller.

The accompanying illustrations show a 180 H.P. 2,000 volt, three-phase oil-immersed controller recently manufactured by the Electric & Ordnance Accessories Co., of Birmingham, for the control of a main haulage gear in a South Wales colliery. The controller consists of a high-tension reversing switch for breaking the main stator circuit on all three phases, and of a rotor switch of the barrel type for cutting out resistance in the rotor circuit.

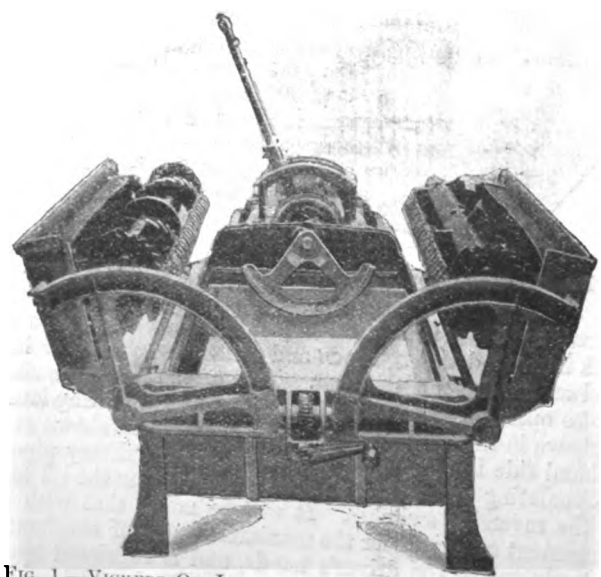

FIG. 1.—VICKERS OIL-IMMERSED CONTROLLER OPEN, SHOWING OPERATING HANDLE.

The rotor switch consists of two barrels mechanically coupled together. These barrels, with their fingers, are mounted on the cast-iron lids, which cannot be shut down unless both barrels are in the "off" position—although when the lids are open, either barrel may be moved quite freely. These lids are hinged to the main frame so as to form a cover for this portion of the controller, and are raised and lowered by means of the handle and worm-gearing shown in Fig. 1. All the contacts and fingers on the rotor barrels are readily accessible for cleaning and adjustment when the lids are raised.

The controller gives 14 running positions in each direction, the resistance being cut out equally in all three phases at each step. The controller is operated by means of the vertical handle, which is provided with a spring catch to prevent unintentionally reversing or starting the motor when returning to the "off" position.

The high-tension reversing switch is of the oil-immersed type, is insulated throughout with porcelain, and is so fixed to the framework that its tank can be readily lowered for cleaning and adjusting the contacts. Although the reversing switch is fully capable of breaking the full-load current, it is so coupled to the rotor barrels that the stator circuit is made before, and broken after, the rotor circuit, so that the reversing switch is never called upon to deal with the full-load current.

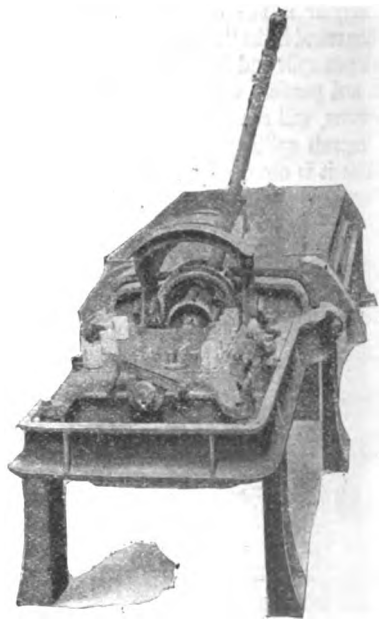

FIG. 2.—VIEW OF THE CONTROLLER IN WORKING POSITION.

The oil tank for the rotor barrel is of welded sheet-iron construction. It is slung by bolts from the framework and is capable of being lowered if required. This, however, should not be necessary, as a plug is provided in the bottom for draining off the oil. To prevent an excess of oil in the tank an overflow pipe is also fitted.

In general, the construction is very substantial and, therefore, specially suitable for its particular duty. Parts liable to wear quickly, such as contacts and fingers, are readily renewable at small cost. Fig. 2 shows the controller in the working position.

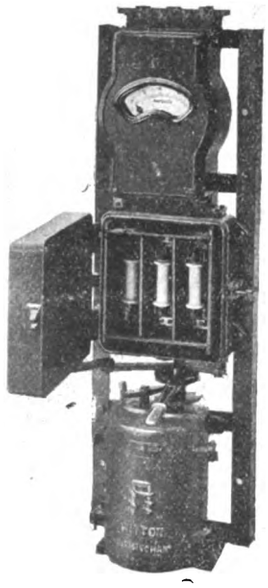
New Three-phase Motor Switch Panel.

Following the example of their well-known "Salford" iron-clad gear, the General Electric Co. have now put on the market the switch pillar shown in the accompanying illustration. The pillar has been specially designed for the control of reversing three-phase motors employed for industrial purposes, but is, of course, with slight modifications, equally suitable for continuous-current motors.

The switch is of the drum or controller type and is very substantial, mica insulation being used throughout. It is contained in a strong water-proof cast-iron case, which is provided with an earthing screw. Another cast-iron box mounted above the switch contains the fuses. This box is also made very strong and its cover is interlocked with the switch handle below in such a way that it can only be opened when the

Digitized by Google

switch is in the "off" position, while it locks in its turn the switch handle as long as the box is open. This interlocking is effected by a strong lever pivoted on the fuse box and linked with the cover so that it swings outwards when the cover is opened and inward when it is closed. The lever is provided on its lower side with a strong steel pin which engages with a cam on the switch handle. This cam prevents the pin from moving outward in any but the "off" position. In the "off" position a slot in the cam is opposite the pin and this latter enters the slot when the cover of the fuse box is opened thus locking the switch handle. The interior of the fuse box is partitioned off into three separate compartments by heavy "Megorine" partitions, thus each fuse is effectively isolated and a "short"-circuit or an "earth" cannot take place. The fuses themselves are the standard G.E.C. porcelain handle Bobbin pattern. The bases which carry the contact clips are of vitreous porcelain. To the upper part of the fuse box an ammeter case is bolted, the joint being water-tight. This ammeter case is as substantial as the rest of the apparatus and ample allowance is made for easy connecting up. The ammeter is



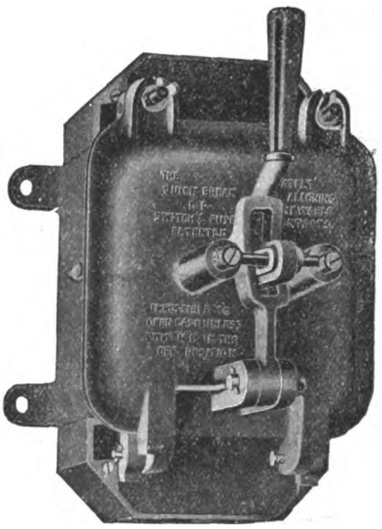
VIEW OF G.E.C. MOTOR SWITCH PANEL.

thus enclosed in an additional cast-iron box and supported on insulation so as to make the clearances of the ammeter equal the clearances of the switch. The whole pillar is of pleasant appearance and it will be agreed that it not only looks, but also is, a thoroughly sound job.

Iron-clad Quick-break Lever Switch.

The ironclad combined quick-break lever switch and fuses made by the Electric & Ordnance Accessories Co. has been specially designed for house service and motor work, but it is equally applicable to mining. Its purpose is to replace the more or less unsatisfactory arrangements hitherto employed, and in itself it is said to be a substitute for the three separate devices almost invariably used for controlling and protecting lighting and motor installations, viz.:—the double-pole open or semi-enclosed main switch and the two single-pole main fuses with their necessary connecting cables. For motor work particularly, the switch has effected a great change in the hitherto generally accepted practice, since first it was put on the market some two years ago. Its water-tight, gas-tight, dust-proof, fire-proof, and fool-proof features are what might be termed critical points in a switch intended for general industrial work, or installed in difficult and perhaps dangerous situations in factories, mills, and it is considered by the makers that the claim that these features are possessed by their switch, is a perfectly reasonable one.

The case of the switch, which we illustrate herewith, is of a fine grain cast iron, asbestos lined, and is provided with inlet and outlet glands, tapped for simplex or other screwed conduit, or untapped and specially rimered to receive the leads. Four lugs are provided for fixing to wall or panel runner. Separate slate bases are provided for each pole, on which are mounted renewable copper contacts and sweating sockets, the bases being thoroughly well insulated from the iron case, and the poles separated by a substantial insulating fillet. The switch lever and all the outside parts are insulated, an earthing terminal being provided. The resistance of the switch is low, all current-carrying parts are of ample capacity, thereby obviating any possibility of heating. The make-and-break mechanism is simple in design, the actual quick-make and break being operated by inclined angle pieces cast solid with the bottom case in conjunction with two special plungers fitted with steel pulleys on the brass switch blade and fuse carrying body. In closing the switch each plunger engages with one of the angle pieces, and is under compression until the apex



VICKERS Q.B. LEVER SWITCH.

of the angle piece is reached; when the compression is released and, due to the inclined surface of the angle piece, the switch blades are rapidly driven home on to the contacts, and a quick-make effected. A quick break is similarly obtained when opening the switch. The lever operates in a loose link; the cover is hinged and asbestos lined, and the switch made water-tight by a rubber gland inserted in the top of bottom case.

The switch, we understand, is mechanically and electrically strong, all working parts being well protected, therefore capable of withstanding hard wear and tear.

Electric Pulley Blocks and Hoists.—A useful serie of equipment for hoisting and transporting loads is that made by the Electric Pulley Block Co. The pulley block used has been specially designed to provide lifting power in positions where, owing to lack of head room or floor space, a crane is not admissible. The block is so designed with worm and wheel that the braking appliances are, it is claimed, unusually simple, reliable and automatic in action. It is supported on a single girder run-way, and the current is supplied from plugs at places where power is likely to be required. Arrangements can, of course, also be made to have the pulley block permanently connected to the mains. It will readily be gathered that this apparatus is both simple and useful, and should find a wide application in all branches of engineering work.

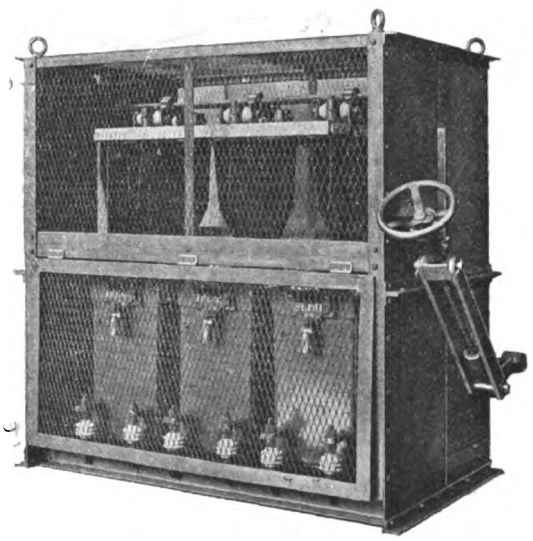
G.E.C. Liquid Starter.

The type of liquid starter made by the General Electric Co. consists of three rectangular tanks each 1 ft. wide, 2 ft. long and 2 ft. high, giving a cubic content of 4 cubic ft. for each pole, or 12 cubic ft. in all. The starter is rated to start a motor which absorbs 400 H.P. during the starting period; this gives, if the starting period is 1 minute, a temperature rise of approximately 25°F. This may seem a very low value, but the fact that starting time as well as starting current are quantities which can by no means be pre-determined must be taken into consideration. For instance, a transmission shaft might be out of alignment or bearings screwed down too tightly or a heavy piece of work might be left in a machine with the tool dead up against the metal which it has to shear off. Any of these or many similar circumstances would cause an appreciable increase of both the starting current and the time taken to start. It is, therefore, absolutely essential that starters, particularly for heavy motors, should be liberally dimensioned.

The three tanks are mounted on strong ribbed vitreous porcelain insulators in such a way that an accurate adjustment is possible. The insulators in their turn are mounted on the channel irons forming the bottom frame. On this bottom frame is built up a complete square framework of angle irons,



G.E.C. LIQUID STARTER FOR USE IN OVERGROUND ENGINE ROOMS.

which is covered with expanded metal screens, while the two short sides are covered with steel boiler plate. The dippers are mounted on another angle-iron framework, which is suspended from a mild steel shaft running the whole length of the starter, and terminating in guide shoes. These latter are guided in slots in the end boiler plates. The whole movable system is counterbalanced with weights by means of steel ropes running over rollers mounted on the operating shaft above. The operating shaft is worked by a 14 in. hand-wheel.

At the bottom of each tank two metal wings are mounted forming a V. The angle of the V is adjustable and the dippers move inside this angle. In this way a very uniform rate of acceleration is maintained through the whole starting period up to the very last, because, as the dippers nearly touch the wings just before the final short-circuiting brushes meet, the last resistance step is very small. This is not so in ordinary liquid starters.

The short-circuiting brushes are of the controller finger type, and are mounted on the short ends of the tanks on bases which also take the cable terminals. The brushes are short-circuited by brass rails fixed to the dipper frame.

The type of starter illustrated is not intended for use down a pit. For this purpose it is totally enclosed in steel to prevent dust getting in. The type illustrated herewith is for use in surface engine rooms.

Fool-proof Fused Switchgear for Mining Service.

Many alarmist reports have been circulated recently regarding the dangers of electricity in the underground workings of mines and collieries. In one of the most recent fatal accidents on record the evidence as to the cause of the explosion centred around one of the switches employed in the mine. For many days this piece of electrical apparatus was held under suspicion, but in spite of the efforts of many of the witnesses to fasten

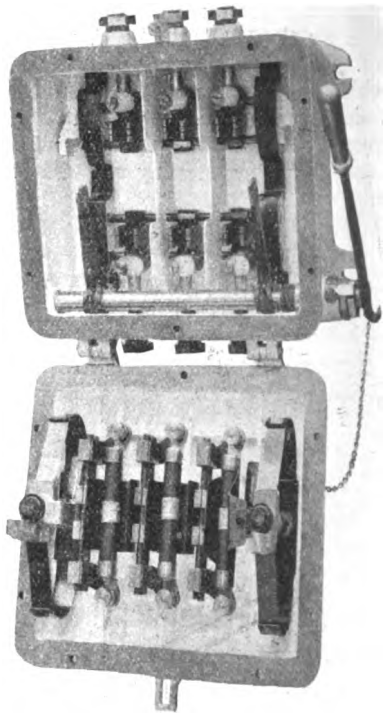


FIG. 1.

upon it the blame for the accident, it was subsequently proved that the switch had operated satisfactorily and was in no way responsible for the disaster. This fact has served to ventilate the subject of electrical control gear for mining circuits. It has brought out into the open the majority of the makers of electrical apparatus who have done their utmost to refute the statement made against their manufactures as a whole,

FIG. 2.

In this particular connection it is of interest to note that the fool-proof fused switchgear of Messrs. Berry, Skinner & Co. has been developed upon lines affording the maximum of safety to the operator in so far as shock is concerned, and almost complete immunity from fire risk due to external or internal sparking. The Berry fused switch has been before the electrical industry for many years, and is well known as an efficient and satisfactory circuit-controlling device. It has been installed to work under almost every conceivable condition and in situations

Digitized by Google

where it is subjected to the attacks of damp or has to resist the effect of fiery or gaseous atmospheres, the latter particularly in chemical works and textile mills. It has also passed the severe tests imposed by the Admiralty and is in use for the control of important circuits on battleships and also on vessels of the mercantile marine.

For colliery and mining service the Berry fused switch goes under the trade name of "Firimine," and we reproduce general views of this in Figs. 1 and 2. These views show a triple-pole switch having a capacity of 100 amperes per way. This switch is suitable for circuit pressures up to 600. The fixed and moving contacts are contained in a substantial cast-iron case. The fixed contacts are of the spring clip adjustable type and are carried in substantial castings which are clipped to mica-insulated steel bars suitably supported at the base of the box. This class of insulation is both fire and damp-proof and has been

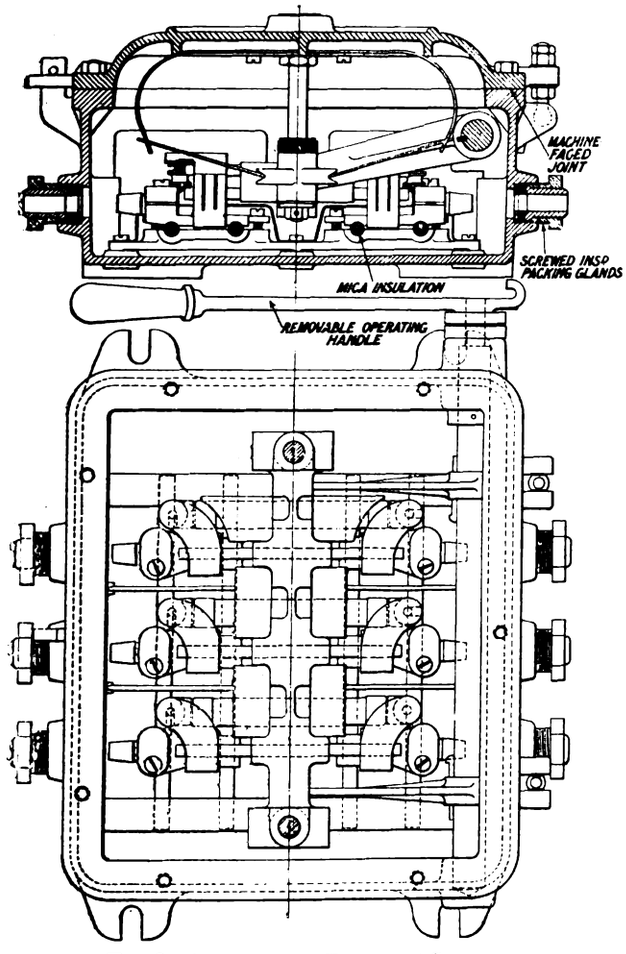

FIG. 3.—DETAILS OF "FIRIMINE" SWITCH.

found to give satisfaction over long periods under severe service conditions. The fixed contacts are separated by uralite partitions. The moving contacts are attached to a carrier which is fitted to guides passing through the lid of the box. Attached to the ends of these guides are flat bow springs with adjustable end pieces. These ensure a quick make and break for the switch. The moving parts are of the solid type and, as in the case of the fixed contacts, mica and steel insulation is employed. The contact blocks are bridged by enclosed non-arcing fuses held in position by milled nuts. This is the standard "Berry" construction.

Special attention has been paid in this switch to the glands for the incoming and outgoing cables, and the switch spindle which comes through to the outside of the box. These glands can all be satisfactorily packed so as to exclude moisture and also the entrance of explosive gas. The joint between the lid and the box has a wide machined surface and 7/8 in. bolts secure these in close contact.

We understand that some tests were recently carried out with this switch at the Armstrong College, Newcastle, due to the courtesy of Dr. Thornton. The interior of the box was filled with a highly explosive mixture, and this was fired by an internal high-tension spark. Although the explosion was severe there was no sign of escaping flame either round the joint between the lid and the box or from the various glands.

The switch is actuated by two swing levers which are securely attached to the operating spindle and engage at their free

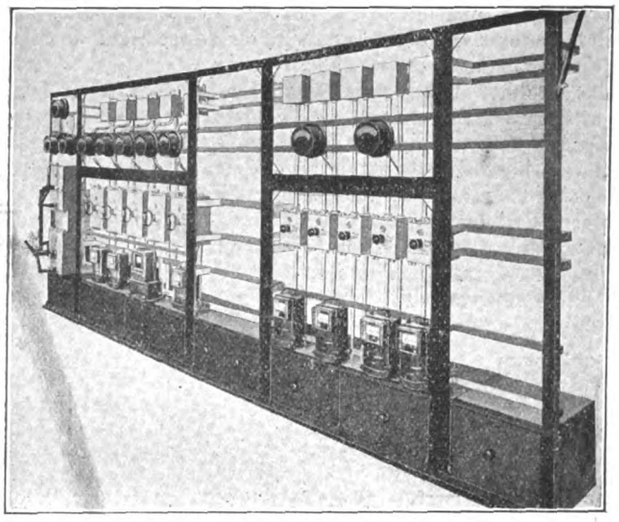

FIG. 4.—TOTALLY ENCLOSED IRONCLAD SWITCHGEAR FOR MINES.

ends with slots in the main carrier. The standard Berry box cover arrangement is included whereby it is impossible to open the lid of the switch when the circuit is made. It is only after the circuit has been broken that the switch can be opened. Fig. 3 is a line drawing showing the general structural details of this switch, and we are sure that it will be of general interest to mining electrical engineers.

Messrs. Berry, Skinner & Co. also make a speciality of totally enclosed ironclad switchgear for the control of low-tension sub-circuits in mines. Illustrations of this are given in Figs.

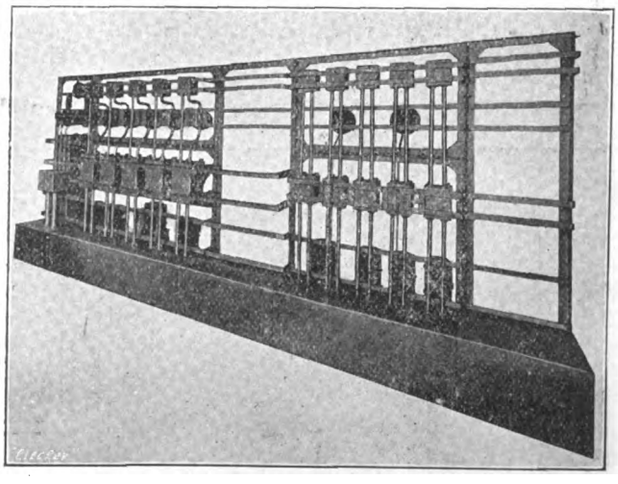

FIG. 5.—BACK VIEW OF TOTALLY ENCLOSED SWITCHGEAR.

4 and 5. It will be noticed that the framework of the board is of angle iron and that the various switches, instruments and meters are bolted up to iron bars at the back of the frame. All the connecting cables are enclosed in steel conduit, which is screwed into the cases forming various portions of the gear. There are no live connections exposed at any point. The connecting cables enter at the top of the board and the 'bus bars are placed in the chamber which will be noticed at the foot. This type of gear is being rapidly developed for use in collieries.

Automatic Pressure Regulator for A.C. and D.C. Circuits.

An interesting apparatus which should be specially useful in mining work is the Brown Boveri pressure regulator, which we illustrate herewith. The principle employed in the construction of this regulator is as follows: The variations in the pressure of the machine to which the regulator is connected are utilised to disturb the equilibrium of a light pivoted armature, which is acted upon by an electromagnet connected across the machine circuit, and the strength of whose field is consequently dependent upon the pressure of this circuit. The torque exerted by the armature with a certain definite field strength is counterbalanced by a spring, so that the armature turns in one or the other direction immediately the pressure, and the field strength corresponding to it, varies from a certain predetermined value. This movement is utilised to vary an adjustable resistance having frictionless contacts in the field

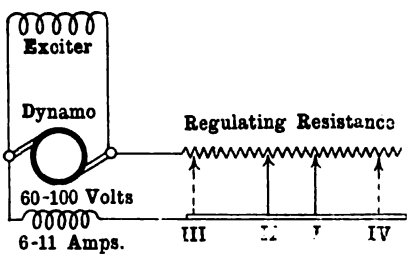

FIG. 1.—DIAGRAM ILLUSTRATING ACTION OF THE REGULATOR UPON CHANGE OF LOAD.

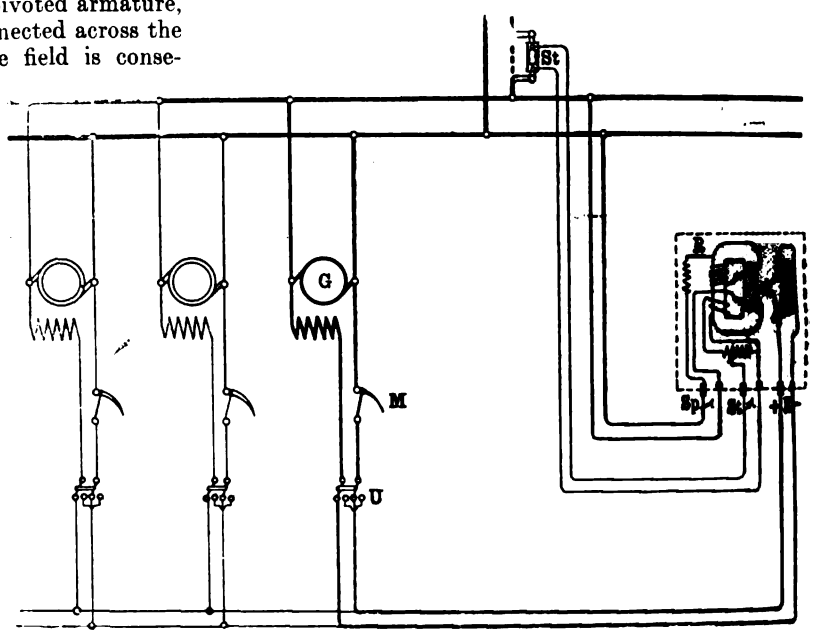

FIG. 3.—DIAGRAM OF CONNECTIONS FOR SELF-EXCITING D.C. GENERATORS.

circuit of the exciter or (for the case of a direct-current machine) in the exciting circuit of the generator, thus regulating the pressure up or down to the required constant value. A damping arrangement is provided, but in order that the retarding effect of the electromagnetic inertia of the field circuit may be as far as possible eliminated, the moving parts of the regulator (which are made as light as possible) are not connected rigidly

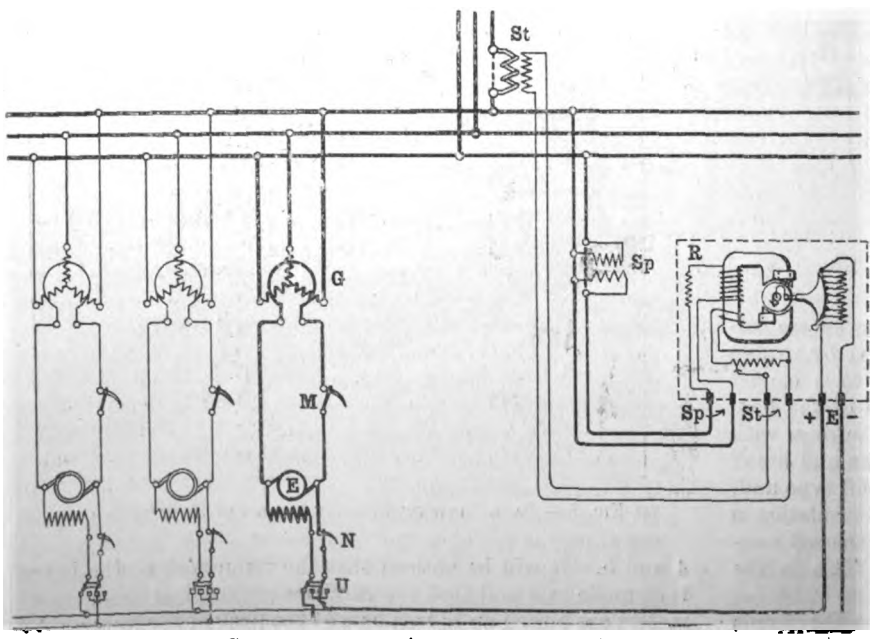

FIG. 2.—DIAGRAM OF CONNECTIONS FOR ALTERNATORS WITH DIRECT-COUPLED EXCITERS.

to the damping system, but are coupled to the latter by a spring. This permits the armature to carry the sectors ahead of the required new position at the moment the generator pressure changes, after which it quickly adjusts itself in such a manner that the field current is brought to the correct value corresponding to the load. These regulators are built in two different patterns—namely, for alternating current (single or polyphase) and for direct current.

The regulator for alternating current consists of a "shaded pole" electromagnet (Fig. 4) which acts upon a cylindrical armature, the latter being pivotted in jewelled bearings. The electromagnet is wound with a fine wire winding, which is connected in series with an external resistance to a pressure transformer. This transformer is placed across the mains; if it is desired to over-compound the generator the electromagnet is provided with an additional winding of thicker wire, which is connected to the secondary of a current transformer, the primary of which is in series with the generator or with the 'bus bars, as the case may be. The magnetic field produced by the electromagnet is dependent upon the pressure on the circuit, and for a definite value of pressure a certain definite torque is, in consequence, produced on the moving system, due to the electromagnetic action between this magnetic field and the armature. This torque is opposed by a flat spiral spring, and as the tension of the latter is dependent upon the extent to which it is wound up, an additional spring is provided, so adjusted that the resisting torque has a constant value for any position of the armature.

The cylindrical armature is made of aluminium for the purpose of reducing its weight and inertia to a minimum, and because of this and because of the lightness of the other moving parts below referred to, the armature immediately follows every variation in the pressure, so that the regulation is carried out almost instantaneously.

The movements of the armature brought about by the pressure variations in the circuit are communicated to a frictionless contact system, consisting of the sectors which *roll* over the contacts, thereby inserting more or less resistance into the field circuit of the exciter. As the exciter field resistances are in series, and the two sectors work together, the amount of movement required to insert or take out a given resistance is reduced by one-half. In order to reduce the amount of friction to a minimum the pivots of the contact sectors are so arranged

Digitized by Google

that the pressures of the springs which carry the jewels neutralise one another, so that in reality the whole contact system is practically frictionless.

With alterations of pressure the spring-controlled armature naturally possesses a tendency to oscillate about the required new position, and in order to prevent these oscillations and yet to allow the armature to carry the sectors momentarily ahead of the required new position a special system of damping is provided, consisting of an aluminium disc, arranged to rotate between the poles of permanent magnets. This disc is driven from the armature by means of a pinion and sector, and a special feature of the damping arrangements is that the connection between the armature and the sector is a flexible one—that is, the sector is mounted upon a sleeve which is coupled to the armature by a flat spiral spring. When the moving parts are in a condition of equilibrium this spring is not in tension, but as soon as the pressure on the circuits alters then, according to the magnitude and direction of the alteration, the spring pulls in one or the other direction according to the direction of movement of the armature, and in this way carries the sector with it. It follows that just at the moment the pressure variation takes place the damping is not operative, thus allowing the armature to carry the regulation farther than is actually required, but almost immediately afterwards the sector follows up the movement of the armature, thus causing the suppression of the oscillatory movements which would otherwise take place.

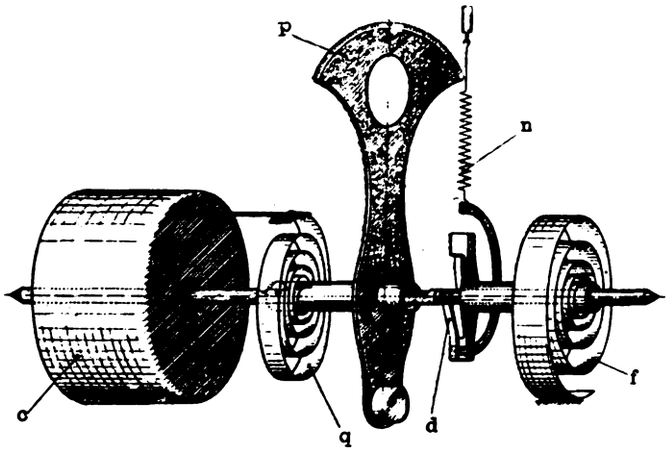

FIG. 4.—DIAGRAM OF MOVEMENT IN BROWN-BOVERI REGULATOR.

This exceedingly valuable feature of the design may be perhaps better understood from the following example. Fig. 1 represents diagrammatically the excitation circuit of the alternator and exciter. Suppose that at no-load the regulator is at the position marked I corresponding to an exciter field current of, say, 6 amperes at 60 volts; at the full load and normal pressure of the alternator the exciter field current has to be increased to 11 amperes at 100 volts and for this the regulator has to be at position II. When the entire load is suddenly thrown on the generator the exciter field current is brought by the regulator to a higher value than that corresponding to full-load by the quick short-circuiting of the resistance, the regulator momentarily taking up the position III. It is necessary for the regulator to take up this latter position at the first moment, because, owing to the self-induction of the exciting circuit and the inertia of the turbine or engine governor, it is necessary to increase the exciter pressure (by cutting out the whole of the resistance) by an amount which more than corresponds to the actual requirements when the steady state has been reached. But immediately afterwards, as the pressure of the generator increases, resistance is automatically and successively inserted into the exciter field circuit until the regulator takes up the correct position II., at which point the period of regulation is at an end. In a similar manner when the whole load is suddenly thrown off the alternator the regulator first takes up the position IV., thus throwing the whole of the resistance into the exciter field circuit, after which it goes back to the correct position I. In each case the effective damping enables the regulator to move into the final position steadily and without oscillation. Such a regulator can also be used for over compounding the machine if desired by providing the shaded pole electromagnet with an additional winding as mentioned above. Fig. 2 shows a diagram of connections for alternators with direct-coupled exciters. With the help of the switches V the regulator can be made to control any one of the machines or one regulator can be arranged to control two or more machines in parallel.

In the direct-current regulator the driving system consists of a wound armature which moves between the poles of a magnet. This magnet is provided with two windings, one of which is in series with the winding of the armature and with the fixed external resistance across the circuit; while the other is provided with an adjustable shunt, and is traversed by a current proportional to the load current. The electromagnetic torque between the armature and the magnetic field is balanced by the resisting torque of a flat spiral spring, and the movement is communicated to contact sectors and a damping sector exactly as in the alternating current case. But it is unnecessary in this case to provide an auxiliary spring to compensate the increase in torque of the spiral spring, as the latter becomes wound up, because the electromagnetic system of the regulator is so designed that the torque on the armature increases by the correct amount, as the angle through which it turns increases. The connections for the direct current regulator are shown in Fig. 3, the current transformer used for the over-compounding winding in the alternating current case being replaced by a shunt *St* in the main circuit.

Liquid Starters and Controllers.

It is usually the opinion of those who have knowledge at all of liquid starters and controllers that such appliances are dirty, bulky and require a great deal of attention, whereas, in properly designed apparatus, the exact opposite is the case. A striking point which will commend itself immediately to users of electric motors is the *smooth* and *even acceleration* obtained by employing liquid starters and controllers. In any other type of starter this essential feature is not found, since a metallic starter has a number of contacts, there are bound to be slight jumps as the resistance is cut out, and therefore slight irregularity in "torque." Another point which is well worth considering, and which is beneficial to the motors and the driven machinery, is the absence of jerks. Furthermore, the upkeep of a liquid starter or controller is practically infinitesimal, as there are no arcing contacts to replace or resistances to burn out. All that is necessary is the occasional supply of clean water when the correct strength of electrolyte has been ascertained. An illustration of switch is given herewith.

This solution is usually made up of a saturated solution of common washing soda, mixed with ½ oz. to the gallon of caustic potash, diluted down to the correct strength, depending upon the function of the motor. A sufficiently near strength for average starting conditions is one part of saturated solution to six parts of pure water; but the exact strength is best determined by actual trial. The solution is correct if a slight sparking is noticeable when the blades come in contact with the liquid, and there is no appreciable sparking at the short-circuit switch.

The most essential feature in the design and manufacture of liquid starters and resistances to secure the best results is the low current-density of all current carrying parts. This should not exceed 20 amperes per square inch of sectional area. Messrs. Tetley inform us that they have tested and seen in use starters calculated at considerably over 100 amperes per square

Digitized by Google

inch density, especially in the blade. Such parts consequently require renewing very quickly, owing to the electrolytic action and burning. Other salient points which should be borne in mind in the design of such starters are simplicity and strength in construction, reliability in operation, safety in manipulation, the provision of slow motion gear as a protective device against starting up too quickly, and automatic features for tripping the blades out of solution.

First cost is a serious item when installing electric plant, and therefore it is necessary to keep expenses down to a minimum in units of 50 H.P. and over; therefore the liquid starter is an item which should receive attention. Below are given a few comparisons between starters of metallic and of liquid types for use with three-phase slip-ring motors.

The price of a 100 B.H.P. three-phase liquid motor starter of capacity up to 150 amperes per phase and enclosed, with a

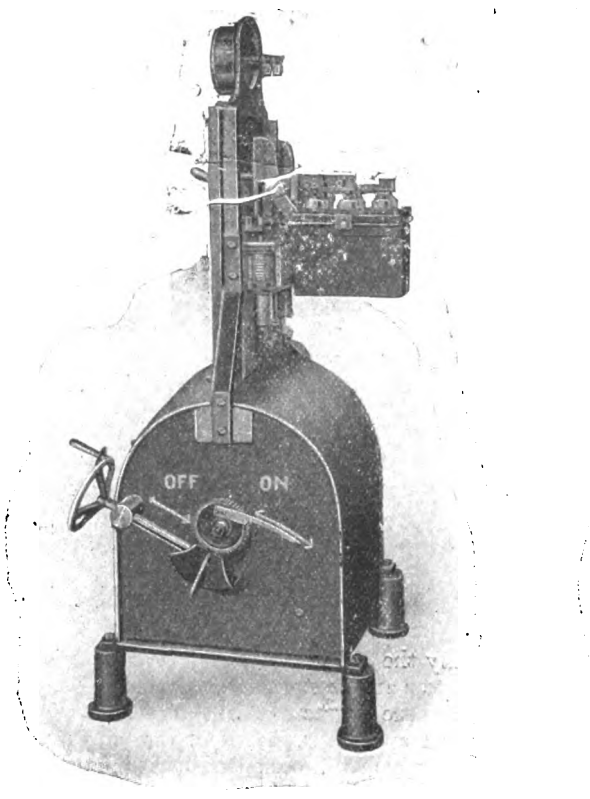

FIG. 1.—TETLEY'S LIQUID STARTER.

maximum rotor voltage of 800, is £10. 15s. A metallic starter costs £20 for 150 amperes, £25 for 200 amperes and £34 for 300 amperes, the price in the two latter cases for a liquid starter being £15.

The construction of a direct-current liquid starter consists of either one or two iron tanks, insulated with porcelain or other suitable material from a substantial iron frame, which holds the resistance liquid, and two electrodes. These latter are slowly lowered or raised from their respective tanks by means of a hand wheel actuated by a worm and wheel. For three-phase starters three tanks and three blades are, of course, required.

The blades are usually insulated from the shaft by porcelain or vulcanite. In the latter case they are painted over with an acid-resisting varnish. The method of securing the blades to the shafts is by the use of a split boss, which is held together by four bolts. *If* it is necessary to renew any of the blades it is only the operation of a few minutes to insert a new one.

Particularly attention is called to the peculiar shape of the blades, which has been decided upon after great experience and a large number of experiments in this direction, the result being that a graduated and a more even passage of current is obtained; consequently the torque of the motors is more constant, owing to the action of this peculiar shaped blade in place of the angular electrode, which, after first making contact, presents too great an area to the electrolyte, and consequently there is too sudden a rush of current to the motor, instead of an evenly increasing flow. The tanks are also tapered to further "balance" the resistance, the idea of which is obvious.

For direct-current work the starter is connected in series with the armature, and in the case of compound or shunt wound motors a resistance switch and discharge resistance is arranged for to take up the field discharge. In the case of polyphase slip-ring motors the starter is connected in the rotor circuit only, and when all resistance is cut out it forms the neutral point of the rotor circuit. It is also usual to fix on the blade a short-circuit switch, so that current will not pass through the liquid (when the motor is running at synchronous speed.) This saves any heating of the liquid and minimising evaporation.

Starters are also fitted with automatic cut-out arrangements, so that if the current fails the blades are automatically tripped from the electrolyte, making the starters practically fool-proof. This arrangement is especially adaptable for textile mills and mines, where the motors and starting gear are remote from the generating station.

The mining starters made by Messrs. Tetley are totally enclosed, and all the flanges are machined and are of broad design. A special outlet is provided for the escape of gases

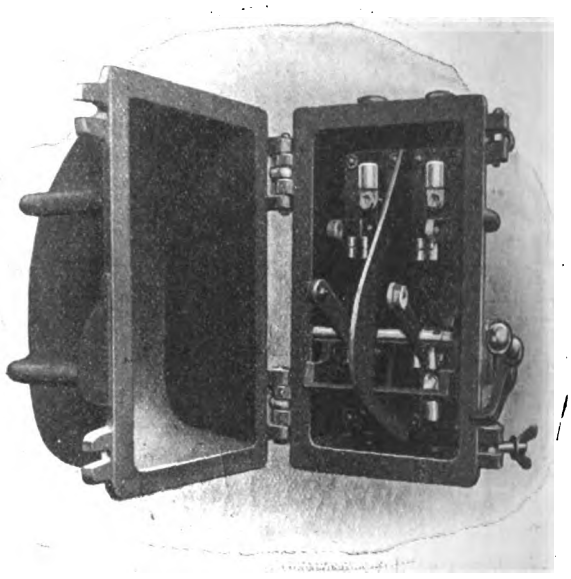

FIG. 2.—TETLEY'S IRONCLAD KNIFE SWITCH.

generated during operation. The circuit is never broken, so that risk of flame is eliminated. In the case of the main rotor switch being connected, this would be oil-immersed and interlocked with the starter or controller by means of a simple brush device, so that the starter cannot be opened unless the switch is in the "on" position, thus doubly protecting the motor and making the starter, it is claimed, "fool-proof."

In the case of large controllers it is necessary to cool the liquid during the operation. This is done by an arrangement of coils in the tanks, through which a constant flow of cold water is pumped or syphoned, the amount approximately being 3 gallons per hour per horse-power controlled. This keeps the temperature as far as possible between 70°C. and 80°C.

In case of an auto-starter it is operated through a slow-speed worm and wheel or ratchet. The worm is always out of gear unless in operation, thereby leaving a free movement to the shaft carrying the blades. All the electrodes are balanced by a suitable weight, and are arranged in such a position that the tendency is to bring the electrodes to the "off" or neutral position, the usual method in adoption for the trips. For large motors, liquid controllers, Messrs. Tetley consider, have a great advantage over the iron type, and they would be more universally adopted by mining engineers if this class of gear was fully appreciated. We are obliged for the above information to Mr. T. R. H. Tetley, of Leeds.

Ellison's Switchgear.

Among mining electrical engineers Ellison's switchgear has a reputation for sound construction combined with reliability and efficiency. The firm has given special attention to the requirements of colliery mining work by designing and placing on the market starting gear as far as possible mistake proof, thereby limiting the risk of accident. A few Ellison specialities are briefly described below.

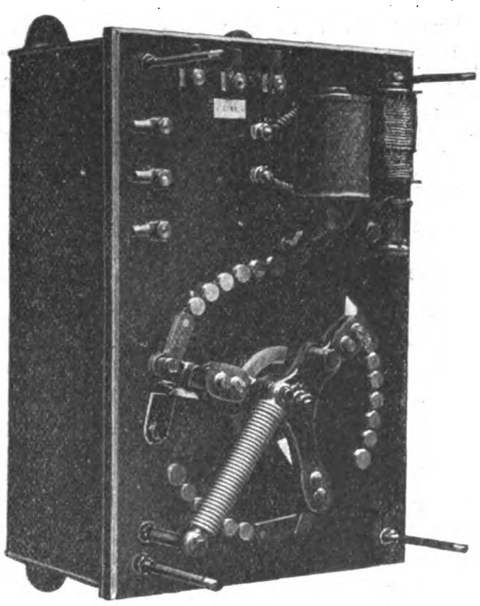

FIG. 1. – THREE-PHASE STARTER WITH OVERLOAD AND NO-VOLTAGE RELEASES.

Fig. 1 shows a rheostatic starter fitted with overload and no-voltage releases for a three-phase squirrel-cage alternating-current motor. These starters are fitted with totally-enclosed covers, glass inspection window, and as they control the three phases of the circuit a separate switch and fuse or circuit-breaker is not required. This type of starter is eminently suitable for colliery surface work.

Fig. 2 shows a totally-enclosed triple-pole air-break circuit-breaker fitted with two overload and one no-voltage releases.

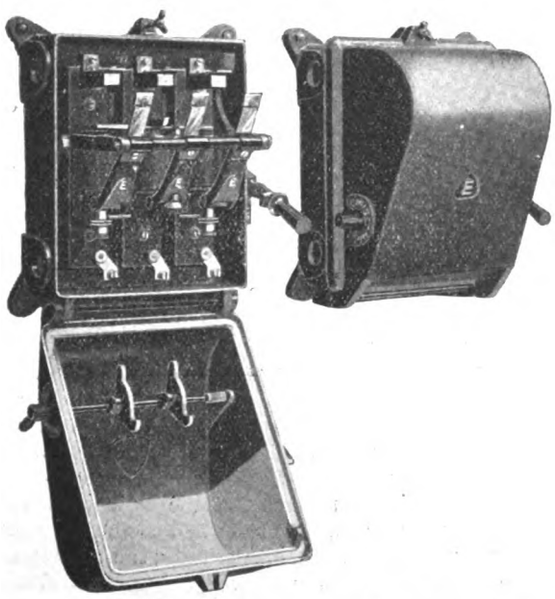

FIG. 2.—TOTALLY ENCLOSED TRIPLE-POLE AIR BREAK CIRCUIT-BREAKER.

This also is designed for surface work. The totally-enclosed overload and no-volt release oil-immersed star delta starter illustrated in Fig. 3 is fitted with patent "Gradatim" safety device. This device prevents the operator putting the starter handle in the running position unless he has first put it at the starting side and held it there a certain length of time to enable the motor to get up speed. As will be seen from the illustration, an ammeter

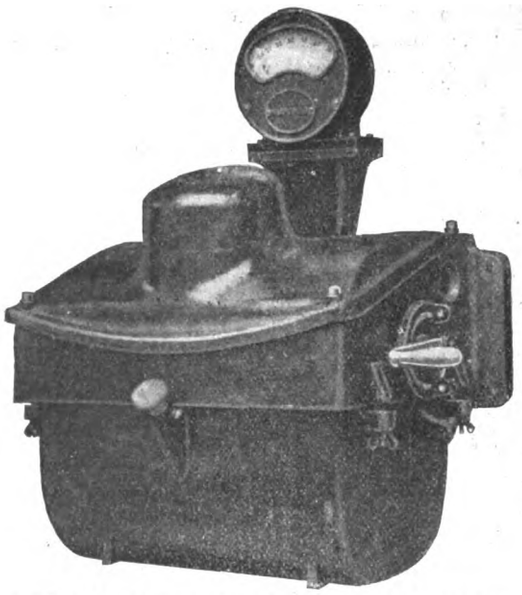

FIG. 3.—TOTALLY-ENCLOSED OIL-IMMERSED STARTER, FITTED WITH "GRADATIM" SAFETY DEVICE.

and bracket can be fixed and also adjustable time lags, if desired. This gear is suitable for installation either above or below the surface. Fig. 4 shows a standard mining panel consisting of a triple-pole totally-enclosed oil-immersed circuit-breaker, fitted with two overload and one no-voltage releases, ammeter and

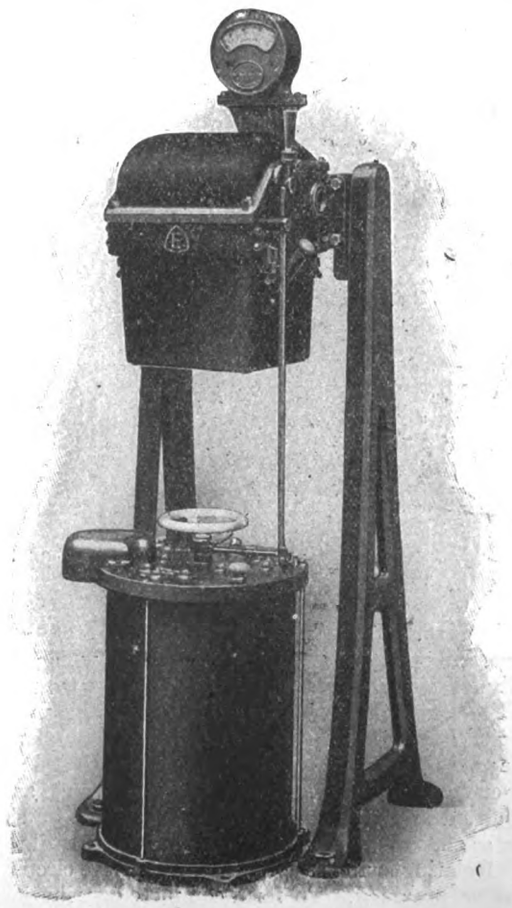

FIG. 4.—STANDARD MINING PANEL.

bracket, mechanically interlocked with a totally-enclosed oil-immersed rheostatic starter. An order has recently been completed by Messrs. Ellisons for 52 of these mining panels.

Protected Switchgear for Mines.

In the Report of the Departmental Committee appointed to consider the working of the existing special rules for the use of electricity in mines, considerable stress is laid upon the protection of switchgear from coal dust, and a recommendation is made that the gear should be enclosed. This gear is evidently to be used in situations where there is no danger of gas and where gastight apparatus would not be necessary.

We illustrate herewith a 50 H.P. continuous-current motor control pillar (Fig. 1) which has been specially designed by Messrs. Engineering Instruments, of Skerne Works, Darlington, to comply with these conditions. This particular pillar provides, it is claimed, complete control of the motor, and is fitted with main switch, fuses, ammeter, heavy duty pattern starter and shunt regulator.

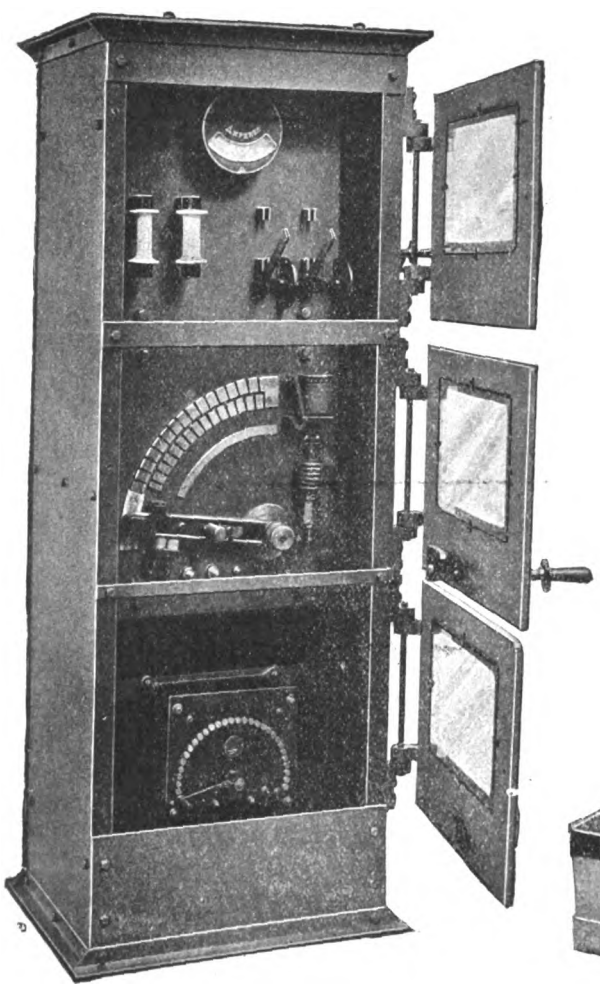

FIG. 1.—50 H.P. DIRECT CURRENT MOTOR CONTROL PILLAR.

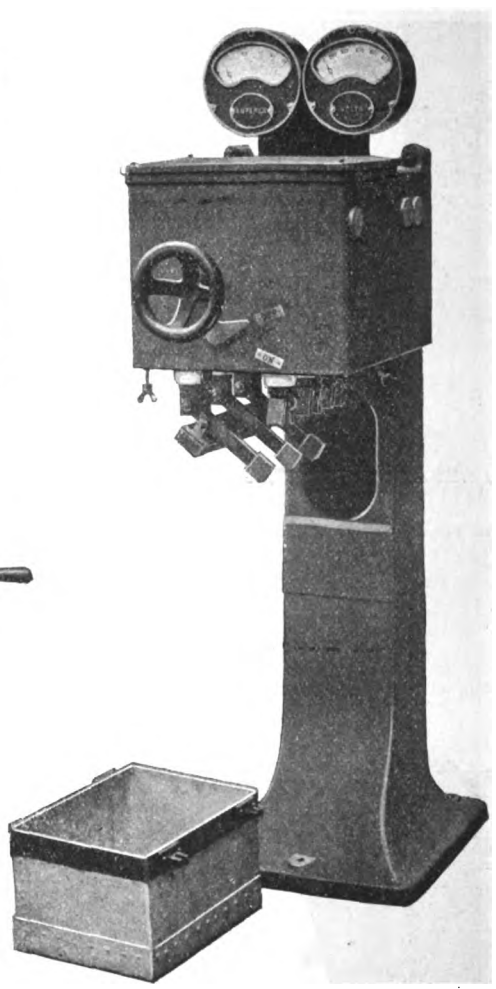

FIG. 2.—THREE-PHASE OIL-IMMERSED MOTOR CONTROL PILLAR.

We also give an illustration of a three-phase totally-enclosed oil-immersed motor control pillar (Fig. 2), which has been specially designed and can be supplied to comply with the special rules. The three-phase oil circuit breaker on this pillar can be fitted with a loose handle no-volt release and overload release in three phases with a time limit, all the trip coils and gear being totally enclosed in the switch casing. Instruments as required can be fitted and an interlock can be provided on the circuit breaker so that the oil tank cannot be removed until the switch is off. Isolating switches interlocked with the circuit breaker can also be provided. To form complete distribution boards the pillars are arranged for bolting together and a 'bus bar chamber is then provided at the back. Trifucating boxes with armour clamping rings are also fitted for the incoming and outgoing cables when required.

Thames Automatic Tumbler Switches.

The Thames Iron Works, Shipbuilding & Engineering Co., have put on the market a special type of switch, known as their "Snap" pattern, having a quick make and quick break action and double contacts. The whole of the working parts are made from hard phosphor bronze and the contact springs of special bronze. The standard design of single, two and three-pole switches are fitted in either brass or cast-iron boxes: the single-pole having a pull and push operating spindle, and the double and triple-pole a turn movement with an exterior lever.

For ordinary voltages up to 250, this switch has, we are informed, a break of such length and speed as to be quite as satisfactory as an open switch, but for high voltages the cases are sealed and partly filled with oil, so that the break is effectively protected by this means. For mine work and for currents up to 10 amperes this little switch is admirably suited, as it is neat and compact and has no flimsy springs or parts to get out of order.

To meet the demand for small automatic circuit breakers, and with a view to offering to the trade something which can be relied upon to open an electric circuit immediately an overload occurs, the Thames Ironworks Shipbuilding & Engineering Co. are now placing on the market what is claimed to be the smallest circuit breaker extant. This they consider should be of great use in places where at present fuses are exclusively used owing to the small currents to be dealt with.

It is a well-known fact that some of the recent disastrous shop fires, such as that which occurred at Brixton, were attributed to the fusing of flexible wires, and as the safety of all electric circuits depends entirely upon an open fuse, which can be tampered with or increased in size by almost anyone, it will be seen at a glance that an automatic switch which operates at the predetermined current for which it is permanently calibrated free of any time element, is a step in advance of any other protecting device. These switches are manufactured under Denny's patents, and we illustrate in the accompanying figures two types of this apparatus.

Fig. 1 shows the switch in section, the magnet being protected by a porcelain covering, and Fig. 2 shows an outside view of the switch with its porcelain covering; the latter type is more suitable for distribution boards and conduit boxes. The object of these switches is to provide a reliable automatic switch for small powers up to 5 amperes and suitable for voltages up to 500. To a large extent these switches replace the ordinary small porcelain bridge-fuses and cut-outs for lighting and small power circuits, and, incidentally, the trouble and inconvenience of replacing blown fuses.

These switches are also admirably adapted for controlling lights either from a distribution board or from separate points. In the former case the distribution board can be fitted with double-pole auto tumblers, or single-pole auto tumblers and single-pole fuses, the fuses being rated about 50 per cent.

Digitized by Google

above the current necessary to trip the switches. In either case the size of the distribution board is considerably reduced and greater efficiency results; should the switches be used at different points in a building a small distribution board is used containing auto tumblers or fuses as the case may be.

In size and appearance the switches are very similar to the ordinary tumbler switch, and are self-contained. They include

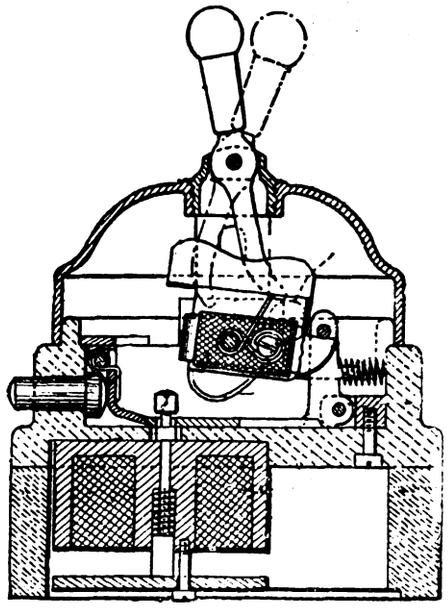

FIG. 1.—SECTION OF DENNY'S AUTOMATIC TUMPLER SWITCH.

a special type of electric magnet, the winding of which is in series with the switch. The armature of the magnet is in direct mechanical connection with a tripping lever, which in turn retains the switch circuit closed in the "on" position. Should an overload occur the armature is attracted by the magnet, and the tripping lever thereby operated, thus releasing the

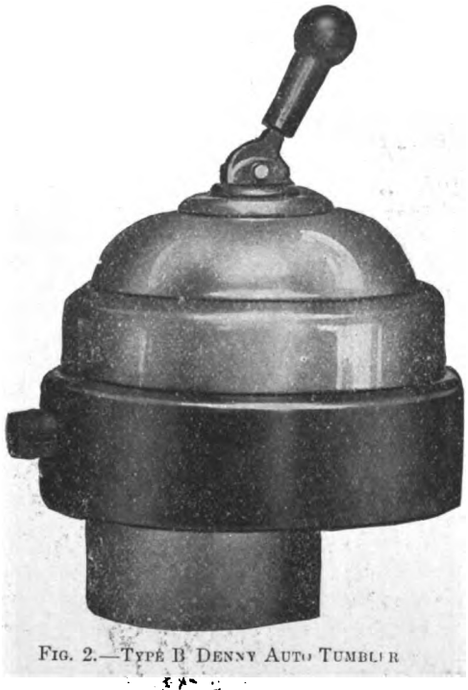

FIG. 2.—TYPE B DENNY AUTO TUMBLER

switch which opens instantaneously, as it has no time element like a fuse. The operating lever is not fixed in any way to the switch parts, so it is therefore impossible to close the switch on a short circuit. To release the switch by hand a push button is provided at the bottom of the switch, which, on being depressed, operates the tripping lever, giving a quick break to the switch independent of the operator.

The use of these switches on high voltage installations, such as electric railways, mines and tramways, should prove economical, as the outlay on cartridge fuses for replacements on these circuits is generally very heavy. The auto switches are also quite suitable and reliable for use as limit switches on a flat rate system of lighting, and can be supplied in various designs and finishes.

"Victoria" Turbo-Pumps.

A comparison between a catalogue of "Victoria" turbo-pumps, issued by Messrs. Jens Orten-Böving & Co. about July, 1909, and one issued by the same firm about 14 months later, makes an interesting study. The first forms, as it were, a "book of prophecy," while the new list just issued, though based on the old, is full of illustrations in the nature of concrete fulfilments of promises.

In the matter of turbo-pumps especially a comparison between guarantees and performance is always exceedingly interesting. The failures of such pumps in the past, especially those for which a high efficiency has been claimed, not only to come up to their guarantees but also to work with any degree of reliability has given rise to a very serious mistrust in the minds of mine managers for whom reliability is a *sine qua non*. Turbo pumps to deal satisfactorily with water under a high head have been very hard to obtain. As a proof of this state-

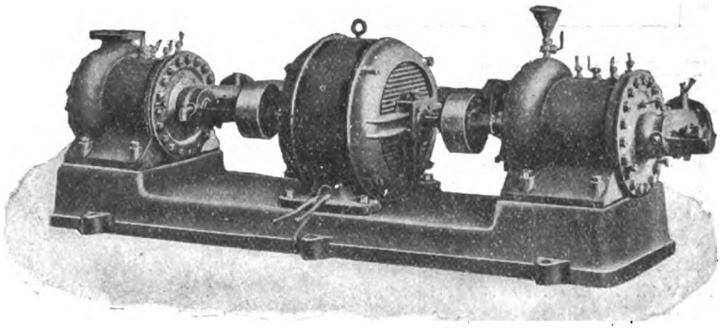

FIG. 1.—TURBO-PUMP SUPPLIED TO THE EAST INDIAN RAILWAY.

ment one need only instance the strong prejudice against turbo-pumps to be found amongst Cornish mine managers, and it is safe to say that hitherto the majority of the orders have been placed on the Continent; at any rate there is no doubt that in cases where price has not been a serious consideration the most notable orders have been placed abroad.

Messrs. Böving & Co.'s new list opens with an illustration of a pump delivered to the Lady Durham Pit of the Lambton Collieries (Fig. 2). Incidentally this was the first order which they obtained in England, and the fact that they were able to secure this order in competition with a well-known Continental firm, is a proof of the confidence which a close study of their designs inspires. The pump delivers 2,900 gals. per min. against a head of 315 ft. when running at 1,170 revs. per min., and although the order was obtained on a guaranteed efficiency of 78 per cent., the actual efficiency obtained on official tests after three months' running reached the remarkable figure of 86 per cent.

The main feature of this pump is that the end thrust is automatically balanced by a simple means which has proved itself during 15 months' work to be absolutely reliable. The secret of the high efficiency lies, of course, primarily in the design of the impellers and guide wheels and casing, which is the outcome of a careful study of the ways of water under pressure as seen in pumps and water turbines; full advantage of this knowledge is taken by the employment of bronze for impellers and guide wheels, as by means of the use of this metal a much smoother surface is secured and consequently a much

Digitized by Google

higher efficiency is obtained owing to the reduced skin friction, and, moreover, this high efficiency is not only obtained but maintained, as the surfaces do not become pitted. The secret of the reliability of the high pressure "Victoria" pumps, in which the pressure is not equalised by double inlets, lies, Messrs. Böving inform us, in the absence of pressure stuffing boxes and thrust bearings. This absence is possible owing to the method of balancing the thrust. There are in this way no bearings to get out of order and no glands which require frequent tightening, which tightening it is well known often results in the cutting through of a large proportion of the pump shaft.

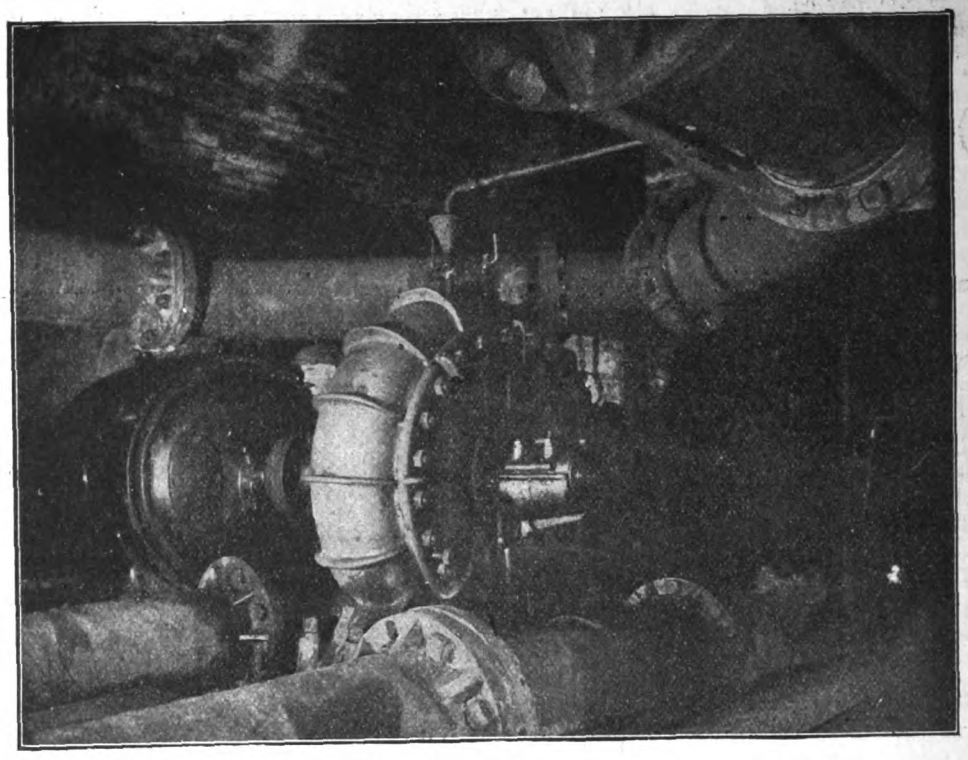

FIG. 2.—PUMP SUPPLIED FOR THE LADY DURHAM PIT, LAMBTON COLLIERIES, TO DELIVER 2,900 GALLONS PER MINUTE AGAINST 315 FT. HEAD AT 1,170 REVS. PER MIN. EFFICIENCY, 86 PER CENT.

Another interesting "Victoria" Pump which has been installed by Messrs. Böving & Co. is one for the Lothian Coal Co. (Fig. 3). It is a well-known axiom for turbo pumps that at a given head the larger the quantity of water delivered the higher the efficiency. The pump referred to is placed at a point 255 ft. below the surface, at which point there is a flow of 680 galls. per min. In the same shaft there is a flow of 150 galls. per min. at a level 155 ft. below the surface. The water at the higher level is collected and passed through the pump 100 ft. below, and is then raised by its own pressure to its own level, and thence raised to the surface by the one pump working at an efficiency of 74 per cent., whereas, if a separate pump were installed at the higher level, the efficiency of this pump dealing with such a small quantity as 150 galls. per min. would be approximately only 65 per cent.

The pump in Fig. 1, which was supplied to the East Indian Railways is another example of solving a difficulty which is frequently met with in cases where it is otherwise desired to employ a centrifugal pump. The difficulty referred to is that of dealing with a small quantity of water against a high head with an economically efficient consumption of power. In the present case, to lift 200 galls. a minute against a head of 535 ft., twelve stages are required, but to supply a shaft of such small dimensions so as not to interfere with the efficient design of the impellers would entail very serious risks from breakage at a critical speed, and even if it did not break the shaft would be "whippy" and cause serious wear. To obviate this, two separate six-stage pumps are installed on either side of the motor, that on the suction side delivering at half pressure and that on the delivery side at full pressure. The efficiency of the pumps so installed is exceptionally high for such conditions, namely, 70 per cent.

A repeat order has just been received from the East Indian Railway for a second pump for the same duties, the first supplied having given every satisfaction. The list also contains

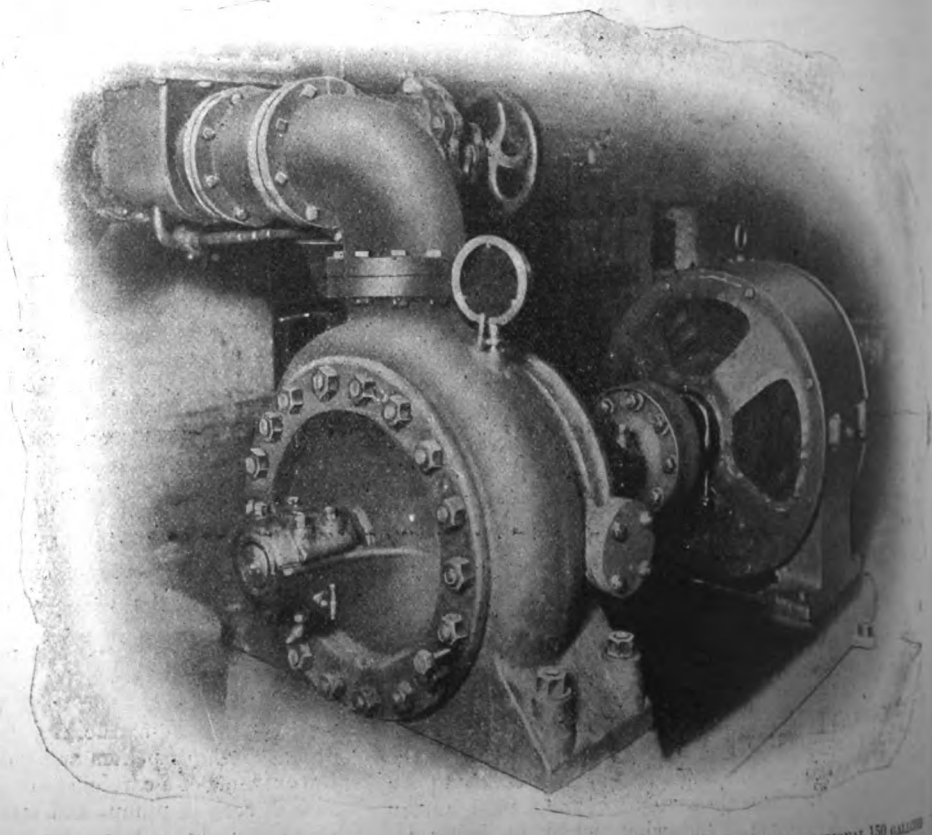

FIG. 3.—PUMP TO DELIVER 680 GALLONS PER MINUTE AGAINST 255 FT. HEAD, AND AN ADDITIONAL 150 GALLONS PER MINUTE BROUGHT DOWN FROM THE 155 FT. LEVEL AND PASSED THROUGH THE PUMP. SUPPLIED TO THE LOTHIAN COAL CO.

Digitized by Google

illustrations of a pumping plant for the City of Toronto (Fig. 4), which consists of four pumps to deliver 9,800 galls. per min. against 250 ft. head and four to deliver 7,000 galls. per min. against 100 ft. head.

A further use for centrifugal pumps for mining purposes is their employment for hydraulicing, and Messrs. Böving & Co. are now supplying a large single-stage Victoria pump to the

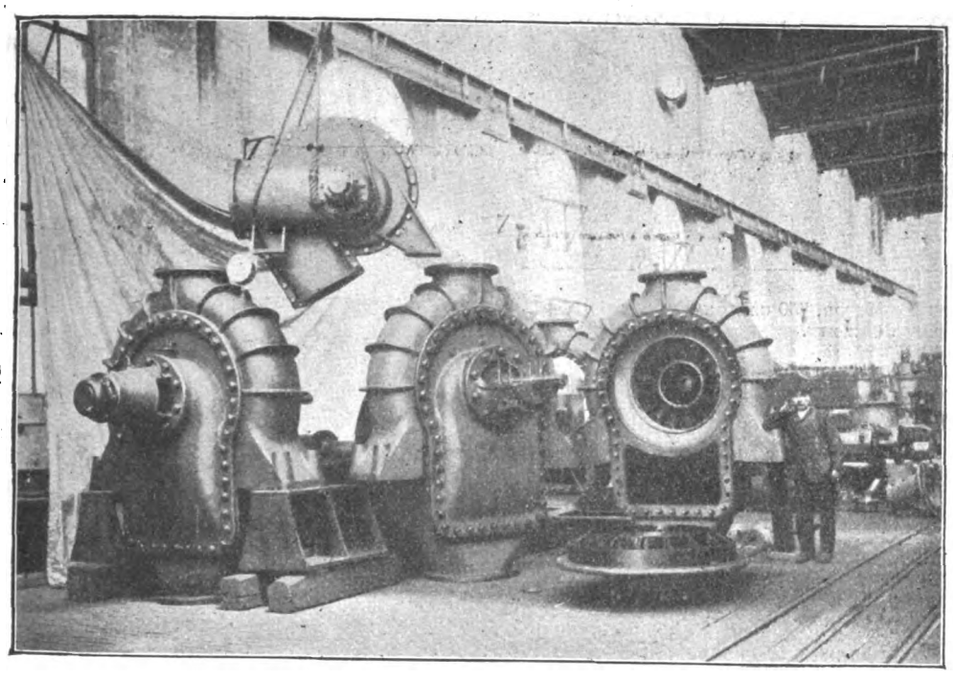

FIG. 4.—PUMPS FOR TORONTO CITY, FOUR TO DELIVER 9,800 GALLONS PER MINUTE AGAINST 250 FT., FOUR TO DELIVER 7,000 GALLONS PER MINUTE AGAINST 100 FT.

Nipissing Mining Co., Canada, to deliver 4,800 galls. per min. at a pressure equal to a head of 415 ft. And in view of the fact that water power is now being much more widely used in generating power in mines, it is interesting to note that this firm have orders in hand or under erection totalling some 120,000 H.P., including six turbines of a capacity of 1,500 H.P. each for the Waihi Gold Mining Co. Being interested in water power, Messrs. Böving & Co. are in a very favourable position to deal with the problems met with in arranging pipe systems in mines, and they have recently put on the market a patented double muff joint, which makes it possible to employ pipes of the same diameter throughout without sockets or flanges and naturally exceedingly simple to erect, while at the same time acting as expansion joints. A large contract for 7½ miles piping fitted with these double muff joints is just being shipped to Mexico, and six of seven complete lines have been shipped to mines on the West Coast of Africa and New Zealand, among other countries. From the above notes it will therefore be gathered that during the period between the issue of the two catalogues referred to in the opening paragraph great practical progress has been made by Messrs. Böving.

B.E.P. Pumps.

The B.E.P. centrifugal or turbo-pumps which are made by the British Electric Plant Co. have been developed along what are usually accepted as standard lines; that is to say, they consist of one or more impellers revolving in a suitable chamber, a guide or diffusion plate being used to reduce the velocity of the water at its discharge from the periphery of the impeller. Thus far the design follows the usual practice, but in the embodiment of the principle of generating pressure by the transformation of the energy of velocity, several very interesting and important deviations are noticeable, chief among which is the patented system of balancing that is employed. An important feature of this system is the entire absence of mechanical means for meeting the great difficulty of axial thrust, which has in the past been a fruitful source of ingenuity to the manufacturer, some of the devices employed being rather of the freak nature, while others have stood the test of practice in a thoroughly satisfactory manner.

When it is remembered that one of the strongest claims made by the advocates of centrifugal pumps is the small number of working parts and the simplicity of the pump as a whole, any means by which this very just claim can be strengthened must go a long way towards bringing this comparatively new style of pump into more general use. As the presence of axial or end thrust has been a retarding factor in its progress by necessitating the presence of what are, in the B.E.P. pump, superfluous parts, the removal of this weak point strengthens its hand in its struggle against its older rival, the displacement

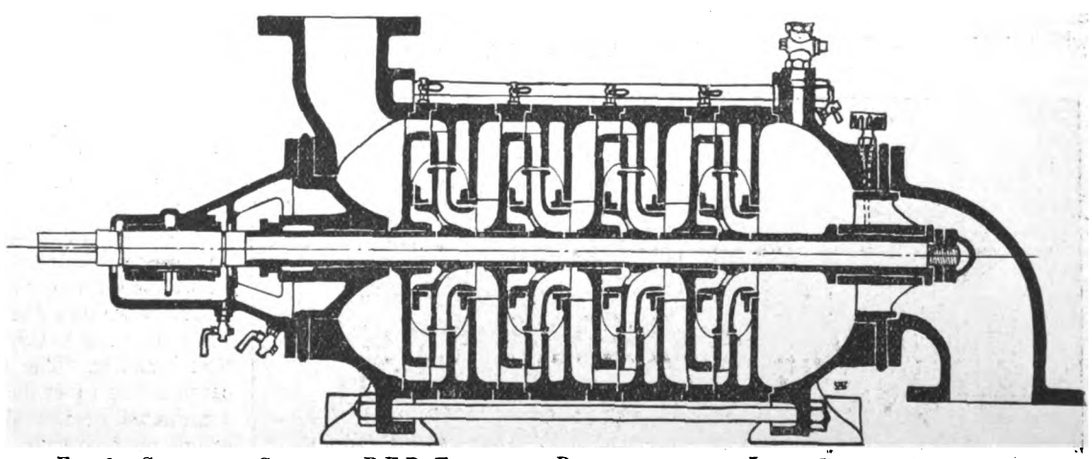

FIG. 1.—SECTION OF STANDARD B.E.P. FOUR-STAGE PUMP SHOWING THE LARGE BEARING SURFACES OF THE IMPELLER NECK RINGS, RENEWABLE NECK RING BUSHES, ABSENCE OF MECHANICAL BALANCING ARRANGEMENTS AND GENERAL SIMPLICITY OF DESIGN.

type of pump, and should materially assist in bringing it into more general favour.

The method by which this result is attained is the acme of simplicity and undoubtedly this is one of its strongest recommendations, as simplicity, as a rule, is synonymous with reliability. The simplicity of the pump is at once apparent

Digitized by Google

at a glance (*see* Fig. 1) at its composite parts. Very noticeable is the absence of ball or thrust bearings or balance pistons such as are usually fitted, their place being taken by very unpretentious looking collars which serve the purpose of controlling the end play of the shaft, and keeping the impellers exactly opposite their respective ports on the diffusion plates.

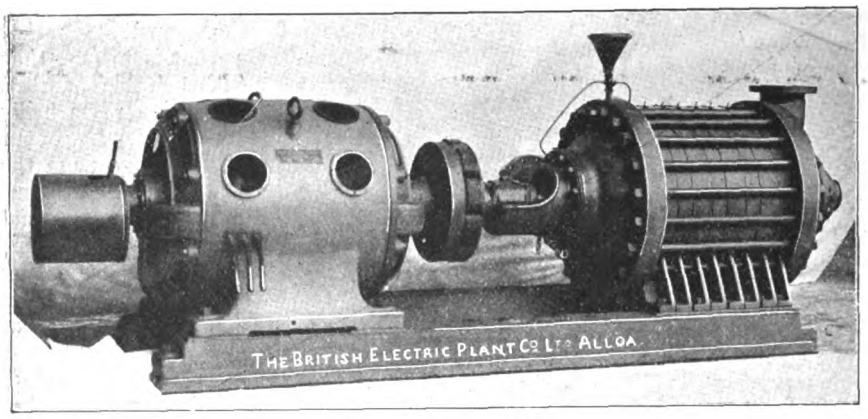

FIG. 2.—B.E.P. FOUR-STAGE PUMP AND SLIP-RING MOTOR, 750 GALLONS PER MINUTE, 660 FT., 240 H.P., 1,470 REVS. PER MIN.

The arrangement of the waterways in the castings is also worthy of note as they are so placed that the entire path of the water is in view for inspection. This is accomplished by making all castings, with the exception of the impeller, open, *i.e.*, without cored passages, and consequently all channels are exposed on dismantling the pump. The simplicity of the castings is striking, and this point should appeal to all engineers who have to deal with the repair and upkeep of machinery underground. A further advantage attendant on this design is the extent of the bearing surfaces, these being specially long, thus ensuring a maximum volumetric efficiency by reducing to a negligible quantity leakage between volumes of water which are at widely different pressures.

Special attention has also been directed to the making of vulnerable parts renewable, and it is possible to fit spare parts, which will practically renew the life of the pump, an indefinite number of times, or at least, till such time as the chamber castings are no longer in a fit state to continue in service, corrosion so reducing them in thickness that they are unable to withstand the working pressure. Even under these, the worst conditions so far as life is concerned, the efficiency of the pump can be maintained at its maximum with only a trifling cost in renewals. These renewals comprise, as a rule, the following parts, some of them of course being more susceptible to wear than others:—Impellers, diffusion plates, impeller neck ring bushes, chamber centre bushes, and shaft sleeves, the last named acting as distance pieces between the impellers and serving to protect the shaft from corrosion and from wear in bearings, no part of the shaft whatever being exposed to the water or being in immediate contact with supporting bearings.

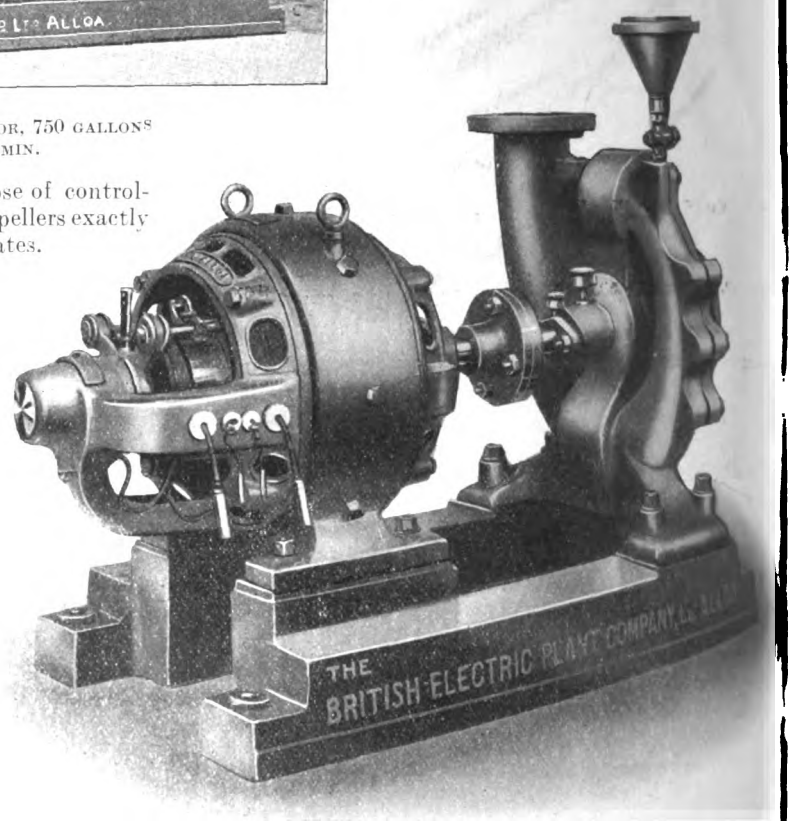

FIG. 3.—B.E.P. MOTOR-DRIVEN SINGLE-STAGE PUMP. OUTPUT 233 GALLONS PER MINUTE, 35 FT. HD.

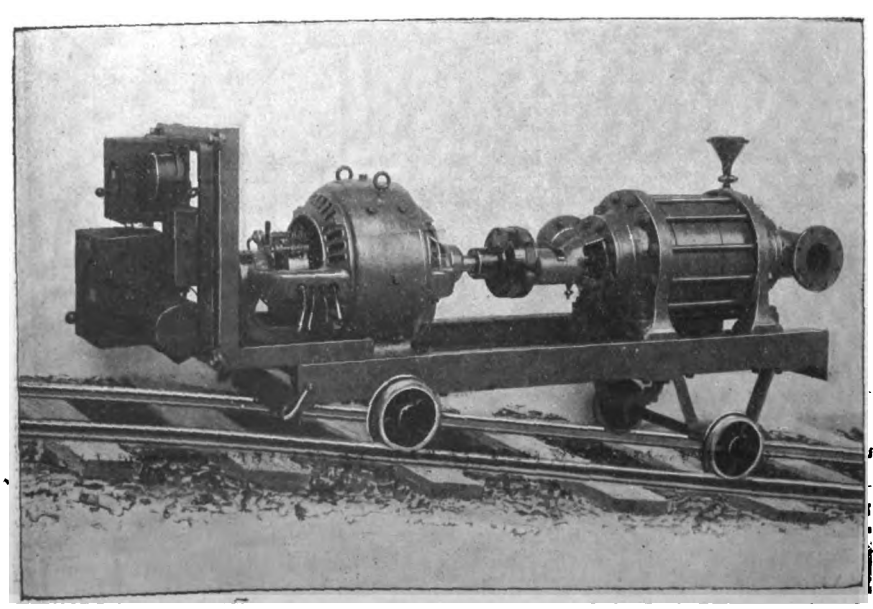

FIG. 4.—MOTOR-DRIVEN PUMP FOR WORKING ON AN INCLINE OF 1 IN 6. DUTY 400 GALLONS PER MINUTE. HEAD VARYING UP TO 220 FT.

By reference to the sectional drawing, Fig. 1, it will further be noticed that the B.E.P. pump is specially suitable for dealing with high-suction lifts, as there is no gland at the suction end of the pump by which air might gain access and so spoil the vacuum necessary to raise the water into the first impeller. The shaft end, protected by a capped nut to exclude water from the thread, terminates in the interior of a tapered bend which may be swivelled into various positions to suit local conditions or requirements of piping. Our illustration, Fig. 2, is of a B.E.P. centrifugal pumping set supplied to one of the principal Scotch coal companies. The 240 H.P. motor is operated from a three-phase, 650 volt, 50 frequency supply, and the pump discharges 750 galls. per min. against a head of 660 ft., the speed of the set being 1,470 revs. per min. Fig. 3 illustrates another B.E.P. standard horizontal pumping set, while Fig. 4 indicates

Digitized by Google

the adaptability of the centrifugal pump to meet special conditions. This illustration shows a three-stage pump and direct-current motor with complete control gear, mounted on a channel iron bogie, this plant being success-fully used for unwatering a dook. By means of special speed regulation and internal arrangement of the pump, the quantity of the water discharged at no time exceeds 400 galls. per min., no matter what the head may be.

Submersible Electric Motor and Pump for Mining Work.

Great trouble has hitherto been experienced in working electric motors in damp places. Particularly has this been so in marine salvage operations, where, naturally, it is an impossibility to keep the plant dry, while often the same difficulty is met with in mines. The Macdonald patent motor, it is claimed, overcomes all these difficulties, for it not only works in damp places, but it will actually work in water without an enclosing case. Messrs. Gwynnes have secured the sole rights of this motor so far as all pumping installations are concerned, and are offering it in connection with their "Invincible" centrifugal pump for marine salvage undertakings, for use on board war vessels and ocean liners; also with the "Invincible" centrifugal pressure or turbine pumps for mines and collieries. There is no need to emphasise the benefits of such a motor in a mine, as with it. sparking is practically impossible, and should the workings become flooded the pumping will not be interfered with.

A typical submersible motor and pump is shown herewith, The motor itself differs from those of the ordinary type in that the stator winding is enclosed in rubber insulation. No attempt is made to prevent the water from getting into the motor; in fact, it is used as a cooling agent, and the permissible temperature rise of the motor is regulated with this in view. A small pipe is also taken from the pump to the motor, and a jet of water, when the motor is not submerged, then plays on the stator laminations in the air-gap. The rotor conductors are so arranged that at no part does the pressure differ by more than 1½ volts from any other part. This also prevents electrolysis.

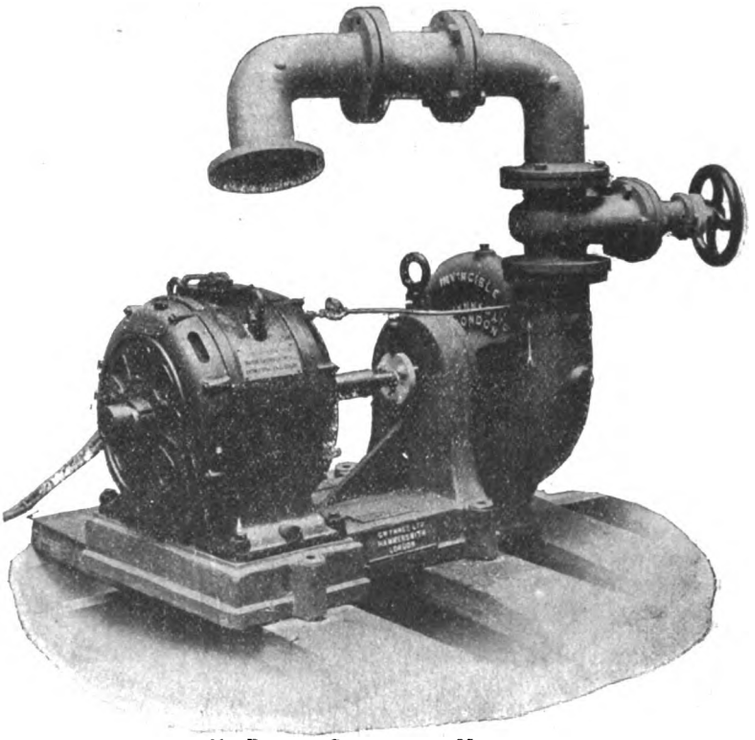
Turning to the application of this arrangement, it is practically impossible to foresee the manifold uses to which this invention can be adapted for mining works. By its means the dangers of mines being flooded and the attendant loss of life are reduced to a minimum. Its usefulness will appeal, we think, at once to all mine owners, civil engineers, contractors and others throughout the world.

For mining work the motor would be connected to a centrifugal or other type of pump of any dimensions and on the same bed-plate or foundation, any sized air compressor can be fitted and connected with the motor. Air pipes can then be led to any part of the workings, however distant, and the operation of a switch at the pit mouth will supply air to any particular place in the mine, although the motor and compressor may be many feet under water. At the same time the pumps can be kept running full bore. Under ordinary conditions the compressor can be utilised to work every kind of pneumatic rock or other drilling appliances and will keep the air perfectly pure in confined spaces where there is the smallest possible outlet.

Another and most important feature of this plant is that, while hitherto it has been impossible to operate electric drills or other electric tools in damp or wet places, the new electric tools constructed with a smaller type of the submersible electric motor can be manipulated under running water, or even entirely submerged, and will run direct from the main motor at any distance from it. This feature will be easily recognised as a great advance and improvement on the present electric tools. The plant is placed at the bottom of the mine or in any convenient position, and the pump need have no lift, simply a delivery to the next stage. In all cases, where possible, the pumping set and motor are submerged in water and, therefore, no suction hose is necessary, simply a delivery pipe, and no priming is required; the pump, being under water, is always primed, ready to start immediately the current is switched on.

In a flooded mine it is only necessary to suspend the pumps by ordinary chain slings from a tackle overhead and immerse them a few feet under water. They require no staging or platforms, there is no vibration, extra lengths of delivery hose are connected up as the water is pumped out and the pump lowered down. It can be pulled up at any time for examination and started again immediately it reaches the water when lowered down. For exploring mines or workings where deadly gases exist, a special helmet and connection from the motor have been devised, enabling the explorer to proceed any distance from the machine in perfect safety. Also by starting the motor pumps by the switches at the pit mouth it will draw out the gas and discharge it at the top of the mine shaft. The recent terrible colliery disasters will conclusively prove the value of a machine of this description, whereby pure air can be delivered to any part of the mine and the deadly gas pumped out at the same time.

Again, if the present type of ordinary electric motors now placed in the mines are flooded from some cause they become



MACDONALD SUBMERSIBLE MOTOR.

useless, the mine is stopped and enormous expense incurred until it can be pumped out again and the motors renewed and replaced; the submersible can be left until an opportunity arises to start the dynamos again and pump the mine out. Probably the greatest feature of the submersible at the present day is that it can be employed for working the coal cutting machines in mines without the slightest danger of any sparking arising from it. Both the motor and switches controlling the cutting gear are simply immersed in a tank of water, the tank being covered in to keep out the coal dust, and the whole arrangement placed on a trolley.

The attention of mine owners, &c., is especially directed to this feature as it will be the means of saving them vast amounts of money. There is at the present time a great feeling of anxiety amongst miners regarding the electrical power appliances in coal mines, which will in all probability develop into an agitation for the complete removal of these appliances except in such cases where submersible motors are employed. The safety of this type of electrical energy can be demonstrated in the simplest possible manner, and will be quite clear to any man possessing ordinary intelligence. The motor or switch being under water cannot spark and, therefore, cannot fire, no matter how gassy the mine may be.

Pumps for Mining Purposes.

Perhaps one of the most important parts of the machinery installed in a mine is the pumping plant. Apart from the question of actually unwatering the mine there are numerous other duties for which pumps are required. The very first steam engines constructed were for this important work, and pumping engines have always commanded a great deal of attention from mining engineers and designers, in order that the best and most efficient results might be obtained from them. Of late years the steam-driven direct-acting plunger pump has been displaced by the centrifugal or turbine pump. Originally the centrifugal pump was only constructed for low lifts, and came into use very largely as a suitable circulating pump for marine engines, owing to its small weight and compactness for the duty performed.

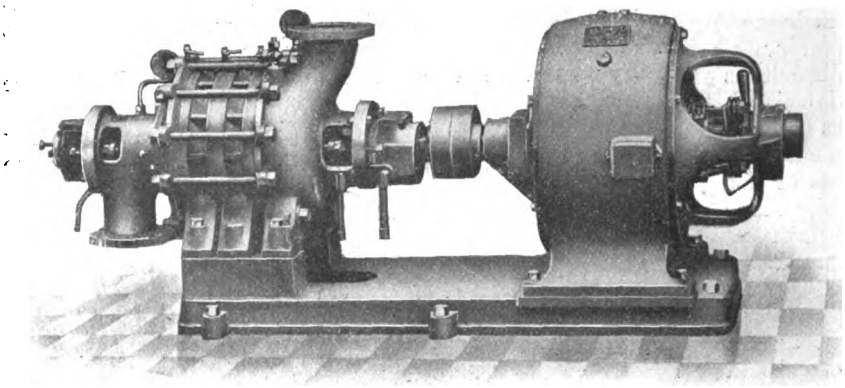

FIG. 1.—"CONQUEROR" HIGH-LIFT TURBINE PUMP.

The last few years, however, have seen the centrifugal pump entering the field of mining, and there taking the place of the reciprocating pump for various purposes in and around the mine, for unwatering, in the power station, in the coal washery, and as a sinking pump during the construction of mine shafts. In conjunction with an electric motor as its prime mover the centrifugal pump, Messrs. W. H. Allen & Co. find, forms an exceedingly portable and compact plant, well adapted for mines as it only occupies a very small space and, moreover, is easily placed in the required position.

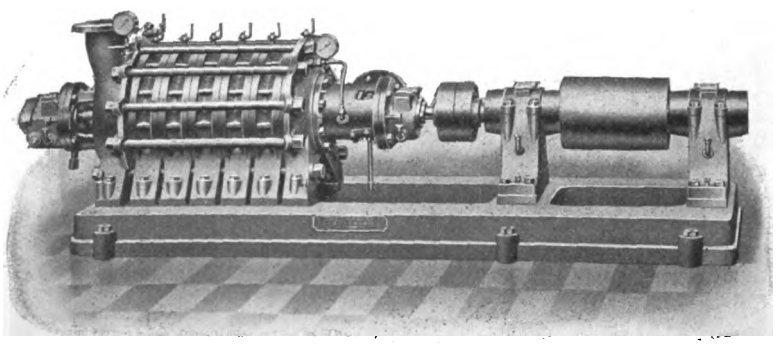

FIG. 2.—"CONQUEROR" PUMP ARRANGED FOR BELT DRIVING.

It might prove of interest to the mining electrical engineer to consider a few of the most recent applications of this class of machinery to mining work. Perhaps the most important class is that of fixed pumps for unwatering pits. Provided that the quantity of water to be raised does not bear too small a relation to the head against which it is to be delivered, the motor-driven centrifugal turbine pump has many advantages over its competitor—the direct-acting plunger pump. The space required is less, the power is applied direct instead of through one or more gear reductions, with their corresponding losses of power, and the water is delivered in a continuous stream: moreover, gritty water may be dealt with, which would soon cause heavy wear on the plungers and glands of a reciprocating pump.

The turbine pump is far more suitable for driving electrically than a reciprocating pump, which is an important point seeing that electricity is the motive power most usually available for driving at the present time.

Fig. 1 shows a "Conqueror" high-lift turbine pump made by Messrs. W. H. Allen, Son & Co., of Bedford. This pump is

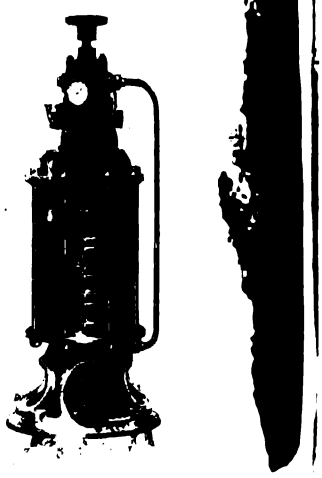

FIG. 3.—VERTICAL FEED PUMP.

capable of delivering 200 gallons per minute, against a head of 290 ft. The pump is constructed in accordance with this firm's usual practice, the outer casing being of cast-iron, the revolving discs and stationary guide-blades being of special tough high-tension bronze, and the spindle of nickel steel. The spindle is fitted with gun-metal liners where it passes through the pump glands, and runs in ring-lubricated bearings which are arranged entirely outside the casing. The spindle is connected to the motor shaft by means of a flexible coupling, and the pump and motor together are mounted on a cast-iron base-plate forming a compact and rigid arrangement. The end-thrust on the spindle is counteracted by means of the firm's patented balancing arrangement, in which the water running to waste is reduced to a minimum; this water moreover serves to cool the pump and motor bearings when necessary. Fig. 2 illustrates a pump of the above type arranged for belt-driving to deliver against 610 ft. head.

The centrifugal pump is now almost invariably used in power stations for circulating the water through the condensers when these are of the surface type, or for extracting the injection water and condensed steam from condensers of the jet type. Messrs. Allen have supplied a great number of their centrifugal pumps, both steam and motor-driven for this purpose. They have paid a great deal of attention during the last few years to the combination of a turbine pump driven by an electric motor, the latter being assisted by a water turbine. This particular arrangement is very suitable for collieries, mines, steel and other works, where water is pumped up to a considerable height, for condensing and other purposes where it is returned to the same level as the source of supply, the water turbine driving the turbine pump by utilising the energy of the water returning from the condenser to its original level. This combination reduces the running cost by a large percentage, and can be economically employed where there is a considerable difference in the levels of the source of supply and the position where the pumping plant is situated.

Figs. 4 and 5 show a combined set consisting of a "Conqueror" turbine high-efficiency pump coupled to an electric motor, and a water turbine, all working on the same shaft. The output of these sets is as follows: turbine pump 2,500 gallons

Digitized by Google

per minute at a 120 ft. head, water-turbine 2,500 gallons per minute at a 101 ft. head. The electrical input does not exceed 54 kw. In this plant the test results were well above the guaranteed figures.

For boiler feeding purposes, in the case of boiler installations where a total quantity of 50 gallons and upwards per minute is required, the turbine centrifugal pump, Messrs. Allen consider,

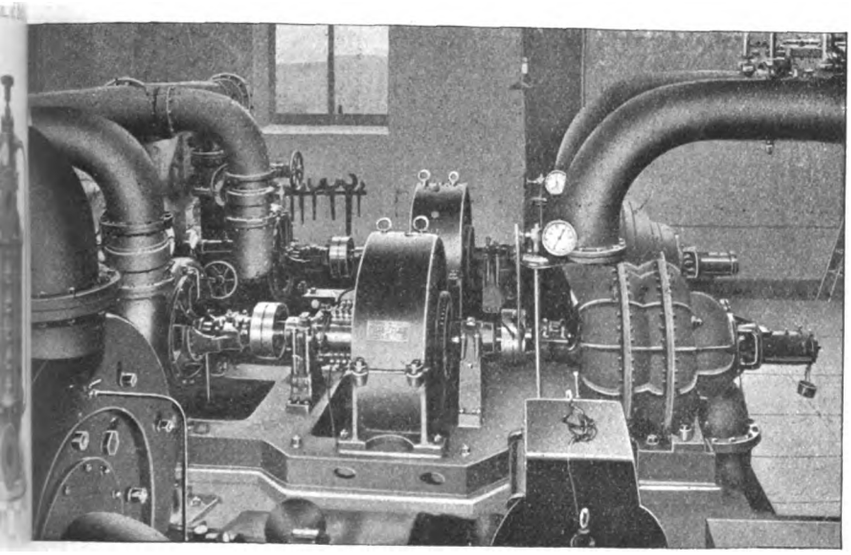

FIG. 4.—THE SAME SET AT WORK.

is eminently suited. The pump can be driven direct either by an electric motor of the continuous or alternating-current type, or direct coupled to a steam turbine. The centrifugal type of pump has many advantages over both injectors and reciprocating pumps. When the water flows to the pump under a small head, it is capable of dealing with the hot feed, and the quantity can be regulated over the widest range necessary, either by a slight variation in speed, or simply by throttling the delivery. Injectors are not only difficult to start, but cannot be used with hot feed water, and require a considerable amount of attention when working. Reciprocating pumps, if of the direct-driven type consume a large amount of steam for

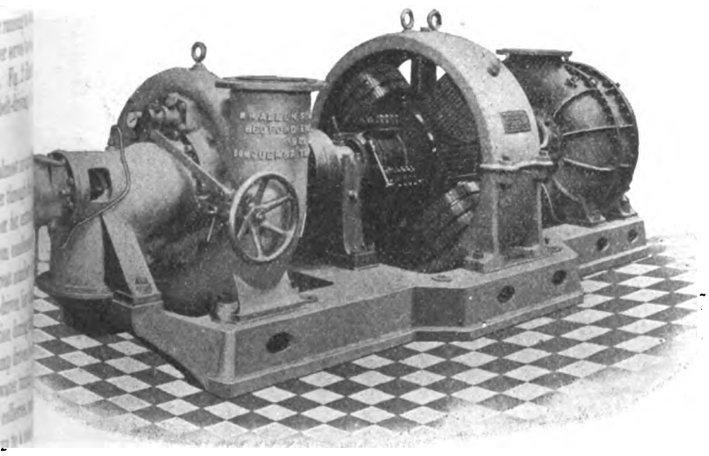

FIG. 5.—COMBINED MOTOR PUMP—WATER TURBINE SET.

the work done; or if of the gear-driven type, are noisy in working, and special arrangements have to be made for a wide variation in speed to enable the quantity to be varied, or some complicated arrangements of gearing have to be introduced to vary the stroke of the plungers. The turbine centrifugal pump is quite silent in working, and delivers a continuous stream of water without pulsation. The amount of floor space taken by this type of pump is very small indeed, especially if made with vertical spindle, as illustrated in Fig. 3, and it will run continuously with a minimum amount of attention, while the efficiency at both full load and reduced load is very high.

Fig. 3 shows a boiler feed pump of the vertical spindle type, motor-driven, which delivers 60,000 lb. of water per hour, against a pressure of 210 lb. per sq. in.

Fig. 6 shows a turbine pump completely dismantled, from which the arrangement and method of construction may be seen.

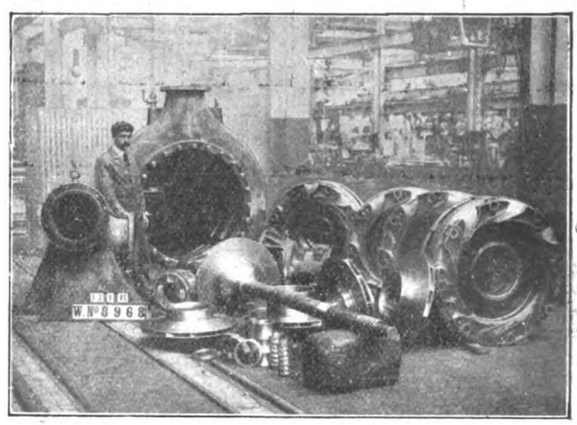

FIG. 6.—DISMANTLED TURBINE PUMP.

Messrs. Allen have also supplied a great many of their high-speed enclosed forced-lubrication engines, and their "Conqueror" counter-current surface condensing plants to many power stations, both for collieries and other purposes.

Electrically-driven Power Pumps.

Owing to the progress recently made in the electrification of machinery in mines there has been a considerable demand for large pumping units driven by electric motors. In this country and on the Continent the development of this class of pumping machinery has taken different lines. On the Continent there has been developed a class of reciprocating pump wherein the motor is mounted direct on the pump crank shaft, driving the latter direct without the intervention of gearing of any kind. This naturally means that the pumps must run at the highest possible speed, and this varies from anything between 100 and 400 revs. per min., depending largely on the size of the pump and the limit the purchaser feels inclined to go to in regard to speed. These high-speed pumps in themselves have very great wear and tear, the various reciprocating parts wearing very rapidly leading to frequent renewal and large expenditure on general up-keep, whilst at the same time the volumetric efficiency of this type of pump is not very high; consequently, the mechanical efficiency is not so good as might be expected. Again, the motors for driving these pumps, seeing that they have, when three-phase current is used, to run at a relatively low speed to obtain the best results, have generally a rather low efficiency and power factor.

In this country, and in our colonies generally, the development has been more on the lines of slow-speed machines. These are very often of the ordinary three-throw type, driven through double reduction of gearing from an electric motor. In a few cases, which we shall refer to later on, slow-speed pumps have been installed driven through single-reduction gearing, this being of the double helical machine cut type, usually arranged to run in oil, the drive being from a motor running at a speed of 400–600 revs. per min. This class of pump has the wear and

Digitized by Google

tear on it reduced to a minimum; the volumetric and also the mechanical efficiency are very high, owing to the small loss there is between the motor and the pump; the motors running at a normal speed give very much higher efficiencies and power factors than can be obtained with slow running machines, so that on the whole this latter class of pumping plant gives much better results than can be obtained with a high-speed pump driven by a slow-speed motor. Another factor which enters

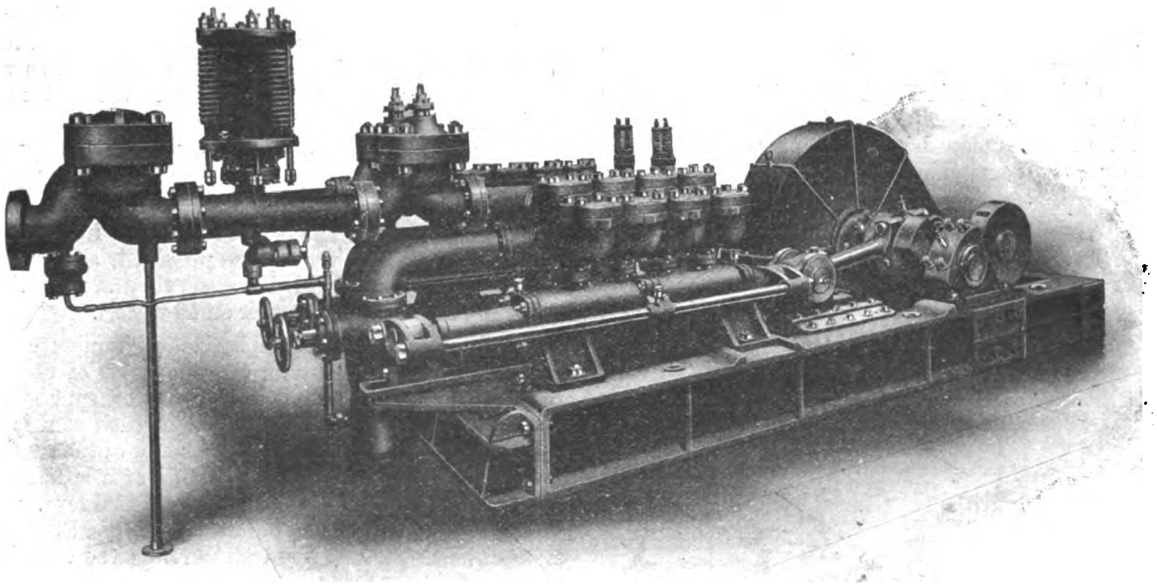

FIG. 1.—WORTHINGTON HORIZONTAL PUMP.

largely into the question of efficiency is that of workmanship. It is a well-known fact that where there is bad workmanship there is also low efficiency, and consequently great wear and tear. With a machine having a high efficiency it may be taken for granted that the wear and tear on it is reduced to a minimum, conditions that can only be obtained by high-class workmanship.

There has recently been built by the Worthington Pump Co., for the Rhymney Iron Co., a type of pump which is considered one of the best for mine service. This machine is of

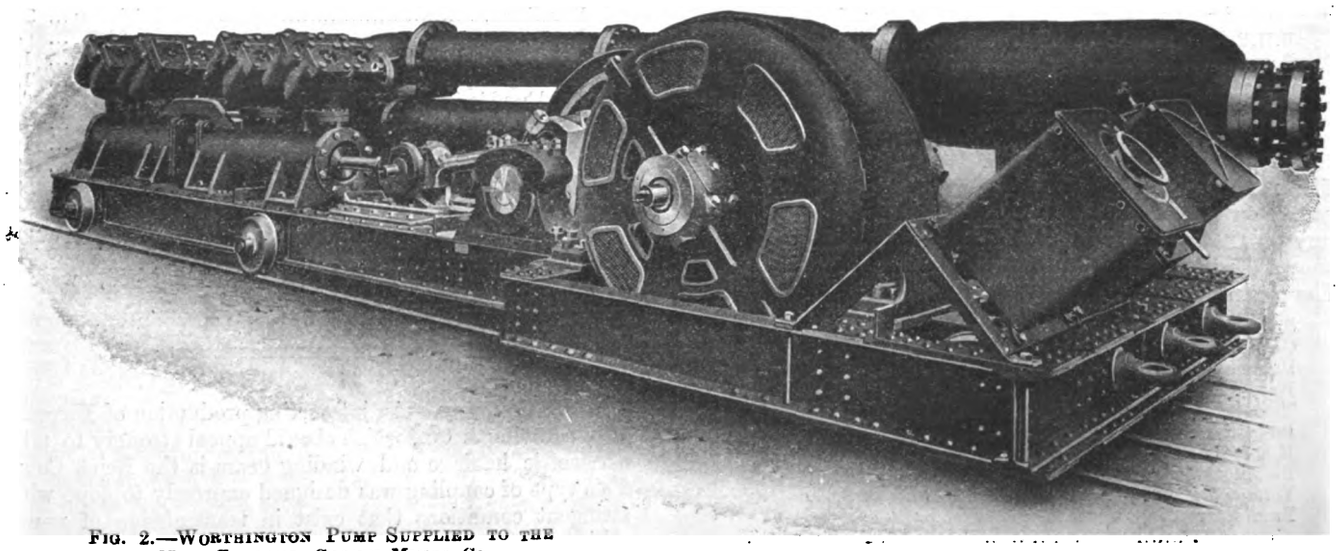

FIG. 2.—WORTHINGTON PUMP SUPPLIED TO THE NEW ZEALAND CROWN MINES CO.

the horizontal duplex outside-packed plunger type, having four single-acting plungers driven, through single reduction double helical machine-cut gear, from a three-phase electric motor. The connection between motor and pinion shaft is through the medium of a flexible coupling. This pump is fully capable of delivering continuously 400 gallons per minute against a total head of 1,815 ft. The pump speed is 38½ revs. per min.

The gear wheel is of heavy construction, having the teeth accurately machine-cut throughout and arranged for a single reduction of gear. The pinion is of chrome nickel steel. The whole of the gearing is totally enclosed in a cast-iron case, which forms an oil bath, the bottom half being securely fixed to the pump bedplate and the upper half being left free so that it can be easily removed at any time for giving access to the gear wheels. The two halves are joined together by means of a suitable planed joint and flanges bolted together. To prevent the creeping of the oil along the crank shaft, two oil-throwing rings of a special construction are provided, and these are so arranged that the oil is thrown into suitable channels formed in the casing and prevent it escaping on to the crank shaft. This casing is also provided with suitable inspection hand holes to enable the gears to be inspected from time to time without having to remove the upper half. On one end of the pinion shaft a flexible coupling is secured, through which this pump is driven from an electric motor.

The pump plungers are of chilled cast iron, accurately ground and polished up to a dead surface. They are securely attached to the respective cross-heads by means of a suitable arrangement of set screws. The pump barrels and valve boxes

Digitized by Google

are of semi-steel, and are made interchangeable, the valve boxes being of the "pot" pattern, having suction and delivery openings joined together into common suction and delivery pipes 8 in. and 6 in. in diameter respectively. In the pump barrels are formed deep stuffing boxes fitted with semi-steel glands and steel studs. The necks of the pump barrels and the glands—that is the parts which come into contact with the plungers—are bushed with gunmetal.

The pump valves are of gunmetal fitted with fibre beats carefully let into grooves formed in them, and they work on gunmetal seats. The valves are efficiently guided and controlled by phosphor-bronze springs.

This machine is illustrated in Fig. 1 herewith, which shows an elevation of this pump.

The guarantee for the motor driving this pump provided that it was to be capable of sustaining a full load run for 24 hours, the temperature rise not to exceed 43°C. It was also to be capable of sustaining an overload of 25 per cent. for two hours and a momentary overload at starting of 80 per cent. without injurious heating of the windings. The full load efficiency of

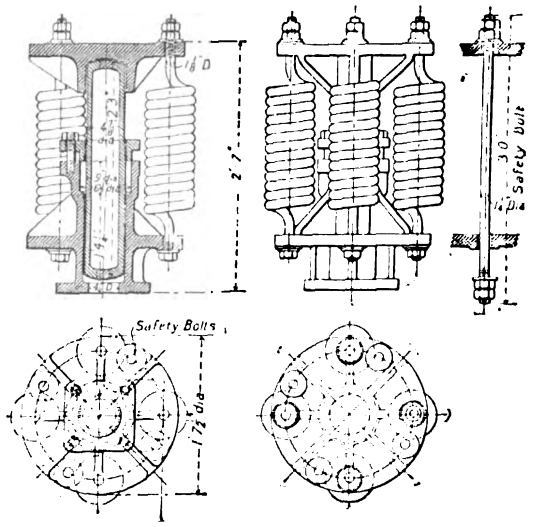

Fig. 3.—Diagram of Alleviator.

the motor was guaranteed to be not less than 91 per cent.

This motor was tested at the British Westinghouse Co.'s works, the following results being obtained :—

B.H.P.	252 ...	276 ...	300
Power factor ...	87 per cent. ...	87·1 per cent. ...	87·2 per cent.
Real H.P.	270 ...	296 ...	322
Real efficiency ...	93·2 per cent. ...	93·2 per cent. ...	93·15 per cent.
Revs per min. ...	420 ...	419 ...	418

The power was measured by an integrating watt-meter. The pressure against the pump was taken by a pressure gauge on the delivery side, corrected for the slight pressure on the suction. This pressure was also checked by the known depth of the mine, so that the figures are very reliable. The pump details were as follows :—

Speed of pump	39 revs. per min.
Gallons pumped per minute	412 gallons per min.
Pressure on the delivery gauge	785 lb. per sq. in.
Head on the suction side.....	4·6 ft.
Total head against the pump	1,808·73 ft.
Pump horse-power	226
Kilowatts	201·6
Electrical horse-power.....	270·24
Voltage (constant)	3,000
From the readings taken the power factor came out at	87 per cent.
which agrees with the test made on the motor as given above.	

Taking the efficiency of the motor as 93·2 per cent., as obtained on the test above, the motor was consequently developing 251·8 B.H.P.

Therefore the pump efficiency was 89·8 per cent., the overall efficiency of the motor and pump being 83·6 per cent.

The alleviator shown in Fig. 3 is a mechanical substitute that has been developed by the Worthington Co. during the last 10 years for the purpose of taking the place of air vessels on pumps working against high pressure. Air vessels for pressures above 600 ft. are difficult to keep properly charged, and mean a separate air compressor to do the work efficiently. The adoption of this apparatus gets over the trouble very effectively, and such apparatus is now working up to a pressure of 3 tons to the square inch with the best possible results. The ram of the alleviator reacting on the steel springs with which it is fitted takes up the pulsations communicated to the water due to inequality of flow or other cause, and so relieves the shock on the pumps and transmits to the motor much more uniform turning moment.

Another machine of practically the same type, but modified in some particular respects to meet the conditions in regard to the capacity and head against which it works, was built by the Worthington Pump Co. recently for the New Zealand Crown Mines Co. Two of these were provided, and from the illustration (Fig. 2) it will be seen they are of the portable type and supported altogether on 16 wheels.

These pumps are of the horizontal duplex centre-packed plunger type, driven by an electric motor of the three-phase induction type through double reduction spur gearing. The stroke is 18 in., and the diameter of each ram is 12 in., the speed 42·6 revs. per min. The diameter of the suction is 14 in. and delivery 12 in. The motor runs at a speed of 364 revs. per min. and the speed is reduced to 42·6 revs. per min. by two trains of gears. The pumps are designed to work against a total head of 500 ft., and all parts on the two sides of each pump are interchangeable.

Each pump and motor with switch and starting appliance is self-contained, and is mounted on a substantial underframe provided with wheels or rollers, to run on rails 2⅝ in. high and a tread of 2 in., so that the whole may be hauled up the shaft in case of accidents.

The following are the particulars of a test that was carried out at the maker's Newark works on these pumps. Each pump was designed to deliver 1,135 gallons per minute against a total head of 500 ft. They were submitted to a running test, one pump being tested when running at half-speed and discharging the water at the maximum head, whilst the other one was tested running at full speed and discharging at half the head. Particulars of these tests are as follows :—

Duration	5 hours ...	3 hours
Revs. per min of pump	21·7 ...	43·0
Gallons per minute (measured over weir)	600·0 ...	1,200
Ditto (by displacement)	613·0 ...	1,213
Total head in feet.....	499·71 ...	261·5
Pump horse-power	90·9 ...	95·15
B.H.P. developed by motor	107·6 ...	106·5
Volumetric efficiency, per cent.	97·8 ...	98·9
Pump efficiency, per cent.	84·5 ...	87·8

The whole of the above figures are mean values of a series of readings taken every quarter of an hour during the process of the trial. The conditions, once established, were very uniform and varied very slightly throughout.

Reich Coupling.—An interesting production of Messrs. Jens Orten Böving & Co., which should appeal strongly to all users of electric haulage and winding gears is the Reich Coupling. This type of coupling was designed expressly to cope with the stringent conditions that exist in transmission of power for rolling mills, haulage gears, and, in fact, for all cases where heavy shocks and frequent reversals are to be expected. The coupling consists of an inner and an outer half together with a detachable ring. The inner half has large claws which fit into recesses in the ring. Between these claws and the outer ring are fitted especially elastic blocks. These are found to fulfil every requirement as regards flexibility, and are at the same time the best medium for transmitting the large powers present.

Common Sense Boiler Design.

BY W. H. CASMEY.
(Of the Yorkshire Boiler Co., Ltd.)

The materials used in the production of steam are coal, air and water, and the reason why greater scientific progress has not been made in steam generators is entirely due to believing that our predecessors had studied the subject, and we have unquestioningly followed their lead.

We were faced with the following questions three years ago: Can we increase our boiler duty per unit of space occupied and also increase the weight of water evaporated per pound of coal burned? The answer to the above has now been discovered, and boilers 20 ft. long are to-day giving equal hourly evaporations to boilers 30 ft. long, thus saving floor space and brickwork and first cost of boiler, and not only so, but giving higher thermal efficiencies. A very elementary examination of the subject points out how this apparent paradox is possible, and also indicates how very small is the attention we have paid to the principles which are brought into play in making and using steam boilers.

The first element to consider is coal. That in general use for steam raising contains from 60 to 70 per cent. of fixed carbon or coke, the heat of which is given off radiantly and absorbed by the boiler and brickwork in the immediate neighbourhood of the furnaces—*i.e.*, the front end of the boiler, the gaseous portion passing away as smoke or flame dependent on the conditions of the fires. When air and coal are used proportionately, say 16 lb. of air to 1 lb. of coal, the temperature of the fire surface is approximately 3,000 deg.; but if 24 lb. of air be supplied per pound of coal, and this is the proportion generally adopted, the furnace temperature will not exceed 2,000 deg., the transmission of heat being less than one-third that secured with the smaller air supply.

The third element in steam production is water, and it is well to remember it is a poor conductor of heat, and must either by location or circulation be brought in direct contact with the hot furnace flues. In fact, a flue surrounded with water in a state of active ebullition will transmit over twice as much heat in a unit of time as when water is not moving; hence the reason why a small active heating surface is more effective than a large sluggish one.

The next point to consider in connection with the subject is heat transmission, and, as this is proportional to the temperature difference between the two sides of the boiler plate, it is at once apparent there must be a greater transmission of heat near the furnaces where the heat is generated than further along the flues. The whole position is one of centralisation; coal gives the bulk of its heat off radiantly. The more perfect the mixture of coal and air the higher the furnace temperature, and the greater this temperature the greater is the transmission of heat per foot of surface.

In the Lancashire boiler we have a most interesting case of how the above laws and conditions are not taken advantage of. The boiler is, as a rule, 30 ft. long, and for about the first 25 ft. the flues are parallel and then taper to the rear end, the outlet being as a rule smaller by 6 in. than any other part of the flues, thus reducing the sectional area at the downtake, in the case of a 9 ft. diameter boiler, 34 per cent. Under the above conditions we have a boiler with 44 sq. ft. of grate and which will transmit to 10 per cent. of the boiler heating surface, say, the first 7 ft. of the furnace flues, over 50 per cent. of the total heat contained in the fuel burned and over and around such heating surface is located 200 gallons less water than over the same lineal length of boiler at the rear; also at the latter point the temperature of the gases is the lowest and the heating surface is the smallest and the weight of water per foot run of boiler the greatest.

Such conditions cannot with present-day knowledge be understood as if the temperature of the gases falls 1,000 deg. from the furnace to the downtake. This indicates each square foot of heating surface at the front end of the boiler transmits as much heat to the water as 4 sq. ft. at the rear, and where, as previously stated, is located the smallest heating surface, the lowest temperature of gases, but the larger quantity of water. Without taking account of the increased temperature of the gases at the rear, if the velocity at the downtake is 1,500 ft., the velocity through the furnaces can only be 1,000 ft.; but if we consider the temperature of the gases at the rear we shall find the velocity through the furnaces falls to probably less than one-half the figure just mentioned. There is not the least doubt that the Lancashire boiler would give 10 to 12 per cent. greater evaporation per hour if worked with the furnaces at the opposite end; in fact, the boiler would then be scientifically correct, whereas at present it is quite the opposite.

The Yorkshire boiler, introduced a little over three years ago, has, like the Lancashire, two furnace flues; but here the similarity ceases, as such flues expand from the end of the furnaces to the rear end of the boiler in the ratio of 2 to 3, the total effect being that the water and heat are more proportionately distributed than is the case with the Lancashire.

In a 24 ft. by 9 ft. Yorkshire the first 7 lineal ft. up to working level contains 13,230 lb. of water, and is served by 73 sq. ft. of flue heating surface. In the last 7 ft. the boiler only contains 11,403 lb. of water, but has 163 sq. ft. of heating surface. In the front end, where the heat transmission is four times as rapid as at the rear, there is 195 lb. of water per square foot of heating surface, and at the back end of the boiler 70 lb. per square foot, a ratio of nearly 3 to 1; in the Lancashire the ratio is only 1·6 to 1.

Consider, now, the larger sectional area of the furnace flues at the rear is acted on by the suction of the chimney, and that the smallest sectional area is at the front end, where the furnaces are; we have then through the Yorkshire fires an air velocity 33 per cent. greater than through the fires of the Lancashire boiler of equal shell diameter and working with equal chimney draught at the downtake.

It is scarcely necessary to point out that this increased draught makes it possible to work with thicker fires and to secure more perfect combustion, and also to burn more fuel per square foot of grate; consequently more heat is generated over a limited area to meet the demands of the greater volume of water located over and around the furnace flues; also that it is possible to burn a much inferior class of fuel.

To give a practicable illustration of the above, there is given below some particulars of the actual comparative boiler test carried out at Frickley Colliery by the National Boiler Insurance Co. A careful examination of the three columns of figures in the report of the above test will satisfy the most sceptical as to the utility of expanding the furnace flues. The following particulars of the three boilers above referred to will enable readers to make their own calculations.

—	Lancashire boiler, crown covered.	Lancashire boiler, not covered.	Yorkshire boiler, not covered.
Size of boiler	30ft. by 9ft.	24ft. by 9ft.	24ft. by 9ft.
Sectional area of flues at the front end, square feet	21	22¼	15·6
Sectional area of flues at rear	15·6	19·2	21·0
Draught at end of side flues	0·5in. W.G.	0·5in. W.G.	0·5in. W.G.
Calculated air velocities per minute through furnaces, discarding corrections for temperature	1,411	1,639	1,900
Actual evaporations secured per square foot of grate per hour during test	279·5 lb.	281·5 lb.	306·4 lb.

Assuming each of the above boilers had been fitted with 45 sq. ft. of grate, as was the case with the 24 ft. Lancashire, and that the two short boilers had been covered with non-conducting composition like the long boiler, and the same rate of coal consumption per foot of grate maintained, the respective hourly evaporations would have been as follows:—

24 ft. Yorkshire ..... 15,235 lb. per hour
24 ft. Lancashire ..... 14,000 lb. per hour
30 ft. Lancashire ..... 12,677 lb. per hour

The size of grate area of the Yorkshire was specified as 44 sq. ft., but when the test was made it had only a grate area

Digitized by Google

of 39 sq. ft., and it is interesting to note that even under such unequal conditions the actual evaporations of the three boilers during the last three hours of the six hours' test were as follows :—

24 ft. Yorkshire	37,925 lb., grate area 39 sq. ft.
24 ft. Lancashire	36,700 lb., grate area 45 sq. ft.
30 ft. Lancashire	27,700 lb., grate area 36·6 sq. ft.

Apart from scientific reasoning, it is only everyday common sense to expect the above results, for if we consider the 30 ft. Lancashire, including its water, up to working level as weighing 54 tons, that of the Yorkshire will only weigh 45 tons, and naturally it would not only take more fuel to raise the temperature of the larger boiler to steam generating point, but also proportionately more to maintain it there. From the figures given above it will be seen the Lancashire could not burn sufficient fuel to maintain its temperature in comparison with the Yorkshire, the coal consumption per square foot of grate being 39·8 lb. and that of the Yorkshire 47·8 lb. ; consequently, its evaporation fell proportionately.

It is well worth careful thought that the 24 ft. Yorkshire weighing 20 per cent. less, and with crown uncovered, gave an actual evaporation per hour 16·8 per cent. greater than the 30 ft. Lancashire, or within 3 per cent. of the calculated results given above, and had it been covered with composition its evaporation would have been 27 per cent. greater than the Lancashire.

A 1,000 H.P. engine taking 15 lb. of steam per indicated horse-power, if supplied with steam by two 30 ft. by 8 ft. 6 in. Lancashire boilers, efficiency 58 per cent. using fuel with a calorific value of 12,600 B.Th. U.s, would give an evaporation of 7·5 lb. of water per pound of coal, or 2 lb. of coal per indicated horse-power. Taking, on the other hand, two 24 ft. by 8 ft. 6 in. Yorkshire boilers in place of the above, this type of boiler, for equal evaporation, has 9 per cent. higher efficiency ; therefore the cost in fuel per horse-power would be only 1·72 lb., or a saving of 280 lb. of coal per hour, or, on a week of 56 hours, 7 tons, costing approximately £3, therefore a direct saving of £150 per year.

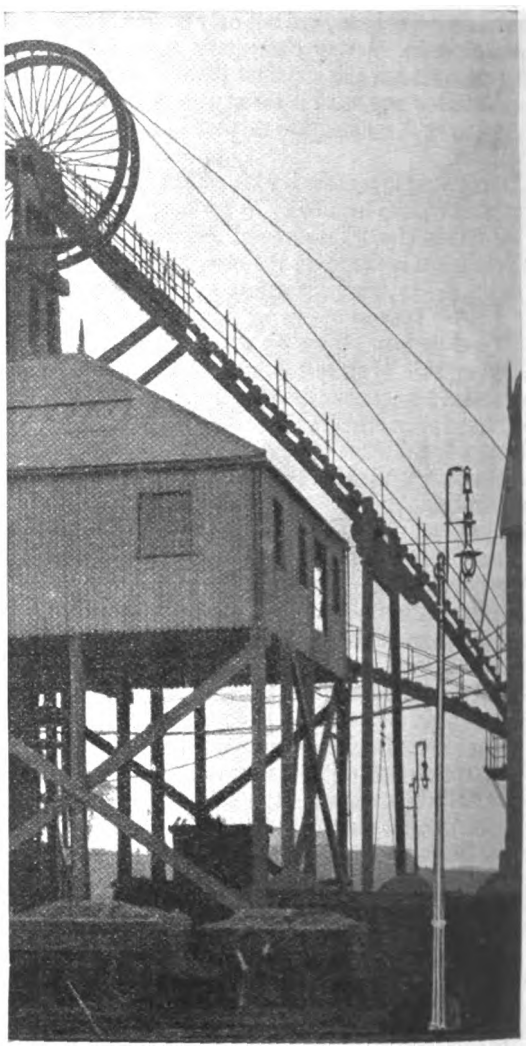
In the production of steam the first essential is a strong draught ; this, as mentioned, enables inferior fuel to be readily consumed ; it also assists in producing a maximum furnace temperature, consequently, a maximum heat transmission, and, such being secured at the front end, a long boiler is unnecessary. One of the greatest authorities on steam at the present time recently stated : "Nothing has hindered the understanding of the law of heat transmission in boilers so much as this fallacious notion that the greater the heating surface the greater the amount of heat transmitted and the higher the efficiency."

Colliery Lighting.

Legislation of recent times, when applied to colliery practice, has, in general, given rise to more efficient artificial lighting for night work. This increased illumination is, of course, necessary in order to produce the best possible results as regards the cleanliness of coal. The introduction of the three-shift system has also involved a very much greater amount of night work, and, as is well known, there has arisen in numerous instances, complaints from buyers as to "dirty" coal. The cause of these complaints has, in many cases, been traced to the inadequate quantity and quality of artificial light used during the dark hours, in lighting up belts and screen houses. This has called for investigation and consequent improvement in the lighting system.

The Jandus Co. has met this demand on various mines by supplying the Jandus regenerative flame arc lamp for lighting. This lamp, with its high efficiency, long burning hours, absence of clockwork, total enclosure and necessitating a minimum amount of attention, has, we are informed, adequately met the somewhat severe conditions under which colliery lighting must be carried out.

For pit head, and large area lighting generally, the light coming off horizontally is important, in order to give even illumination with a small number of lamps. For screen-house and belt lighting, the all important factor is the colour of the artificial light ; the requirements here are exacting on account of the vital nature of the work involved in differentiating between the coal and stone on the belt. In coping with these problems the Jandus Co. have supplied their patent regenerative lamp with chemical carbons to several collieries, among which we may mention the following :—The Washington Collieries, Co. Durham ; The Ryhope Colliery, Co. Durham ; Ouston E. Colliery, Birtley, Co. Durham ; Harton Coal Co., South Shields, Co. Durham ; Chatterley-Whitfield Collieries, Stoke, Staffordshire ; and Sneyd Collieries, Stoke, Staffordshire.



JANDUS REGENERATIVE LAMPS AT OUSTON "E" PIT, BIRTLEY & Co., CO. DURHAM.

The results there obtained have, we understand, fully warranted the owners of these collieries adopting this form of lighting.

The principle upon which the type of lamp at the foregoing collieries operates is that of the use of chemically treated carbons burning in a double enclosure, the chemical vapours being made to circulate again and again through the arc, thus resulting in long-burning hours at one trimming. This action is obtained with entire absence of complicated mechanism, thus involving a minimum amount of attention to the upkeep of the lamp. This lamp has been fully described in our columns and is well known to our readers, while full particulars can be obtained from the makers, the Jandus Arc Lamp & Electric Co., Hartham Works, Holloway, London, N.

Siemens Luminous Mine-shaft Signalling.

Siemens luminous mine-shaft signalling apparatus has been designed to provide a safe and rapid means of communication of orders from the different levels of the mine to the engine house by the addition of visual indications of the orders to the bell signals usually employed. The apparatus consists of sets of indicators and bells for the pit bank, engine room and levels. These parts are illustrated in Figs. 1, 2, and 3, and the method of operating them is as follows :—When it is required to wind men from the level, the onsetter turns the top switch on his indicator to "men," and then gives the customary rings on the bells at the bank and engine-room by means of the bell switch provided. If the banksman concurs with the signal from the onsetter, he replies by means of the bell and turns his switch to "men," whereupon the signal "men" is illuminated in the engine-room, at the bank and at the level. This indicates to the engineman that the men are to be carried, and this order remains in force for all the subsequent windings until it is altered when some other operation has to be carried out, such as "coal" or "shaft," the former being used when coal is to be carried, and the latter when it is required to examine the shaft.

The operations of winding are controlled by the lower switches on the bank and level instruments in the following manner :—If the cages are provided with one deck only and are loaded ready for raising and lowering, the onsetter and banksmen turn their respective switches to "ready," and give the usual rings on the bells. When both have turned their switches the signal appears illuminated at the engine-room, bank and level. It will be seen that the visual indication of the order does not appear in the engine-room until both the onsetter and banksman are ready for the order to be executed. When the engine has started, a switch is actuated which releases the "ready" switches at both the bank and level, thus extinguishing the lamps and the order on the indicators and leaving them clear for further orders. In cases where the cages have two or more decks which are loaded from one staging, necessitating the moving of the cage a short distance after one deck has been loaded, the operation is controlled by turning the switch to "change decks," with the same procedure as for "ready." The signal "change decks" is obliterated by the movement of the engine, in the same manner as the order "ready." When all the decks are filled, the signal "ready" can be given in the same manner as for one-deck cages, as described above.

Messrs. Siemens inform us that any system of bell signals can be used in conjunction with the luminous signals. The circuits for illuminating the indicators being separate from the bells, the indicators form independent corroboration of the bell signals, and as it is necessary for both the onsetter and banksman to operate their switches before the orders are illuminated, it is clearly indicated to the engineman that he may proceed without any possibility of doubt as to the bell signals given. The emergency or "stop" signal can, however, be operated independently by either the onsetter or the banksman, to stop the cage at any point. An important feature of the system is that the bell signals required by the rules are not interfered and can be performed in the ordinary manner. In cases where the bell signalling apparatus already exists, the luminous indicators can be supplied without the bells. In addition to the safety provided by having a visual indication of the order, further security is obtained by the arrangement that the visual indication does not appear until both the men concerned, the onsetter and the banksman, have concurred and performed their part of the signalling. It is also impossible for more than one order to appear at the same time, the changing of an order by either man extinguishing automatically the previous indications.

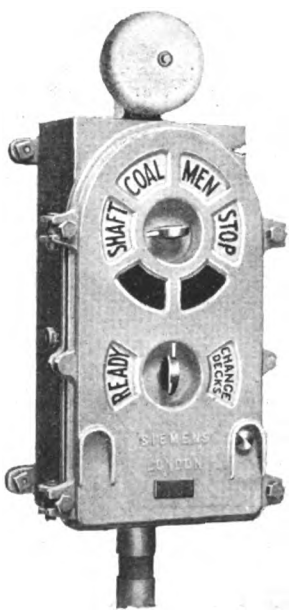

FIG. 1.—PIT BANK INSTRUMENT.

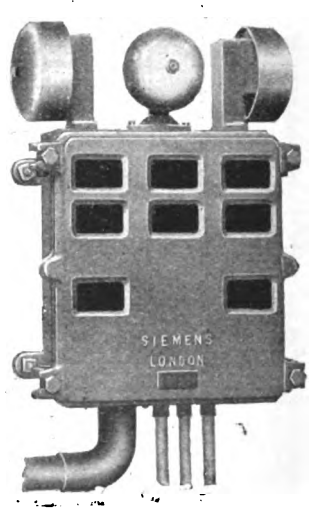

FIG. 2.—ENGINE ROOM INDICATOR.

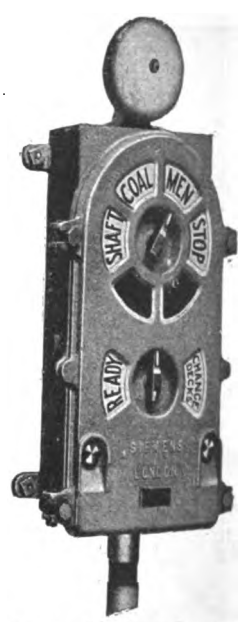

FIG. 3.—PIT LEVEL INSTRUMENT.

A considerable advantage in the direction of simplification and speed of working is, it is claimed, obtained by dividing the visual indications of the orders into two groups, one group comprising such orders as will be standing orders and are required to be in force for a considerable time, extending over several operations of winding, such as "men riding," "coal," &c. The other group consists of the orders on which the engineman acts to raise or lower the cage, and comprises "change decks" (when required) and "ready." The indications of the latter group of orders are extinguished automatically immediately the engine is moved to change the decks or to raise the cage, whereby it is impossible for an order which has been executed to remain and thus to cause confusion.

Visual indications are provided by illuminated windows, on which the orders appear as soon as the lamps, which are arranged behind them, are lit by the operation of the switches at the levels and pit bank. Although the bell signals are independent of the luminous indicators, practically no time is lost in working the latter, since it only requires the operating of the "ready" switch at each winding. The moving of the switch for the standing orders is only required at long intervals. The "stop" or emergency order, when operated at either the pit bank or the levels, immediately illuminates the order on all

instruments and at the same time rings a trembler bell in the engine-room. For this signal it is not necessary for onsetter and the banksman to operate their switches together, as in the case of the other standing orders.

For mines in which there are two or more levels from which it is required to communicate with the engine house, additional sets of indicators are installed under the control of the banksman, to indicate to the onsetters which level to use, and to the engineman to which level to work the cage. Means are also provided in this apparatus whereby only the level to which the cage is working can send orders to the engine house. Each onsetter can communicate to the banksman in order to indicate when he requires the cage to stop at his level. The apparatus is contained in substantial water-tight cast-iron cases, with separate windows for each order. The press switches and the order-sending switches are securely protected, so that it is impossible for them to be accidentally closed.

Messrs. Siemens also make a series of signalling instruments which are adaptable to mining work. A typical transmitter (Fig. 4) and receiver (Fig. 5) are illustrated herewith

An installation of dial instruments in its simplest form consists of a transmitter and a receiver; one transmitter can, however, actuate any number of receivers simultaneously, or, in case every apparatus is provided with a transmitter, orders can be transmitted with each apparatus. The orders to be transmitted, which may be of any number, are marked upon a circular dial over which a pointer is moved electrically. To send any particular order, the pointer of the transmitter is moved, by a handle projecting from the front of the instrument, to the respective section of the dial, whereupon the pointers of all the other instruments move to the same section; at the same time the bells fitted to the instrument ring, announcing a fresh position of the pointer.

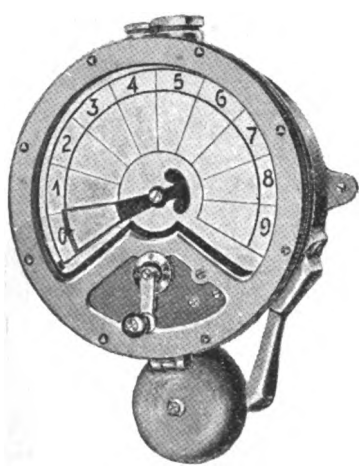

FIG. 4.—SIEMENS TRANSMITTING INSTRUMENT.

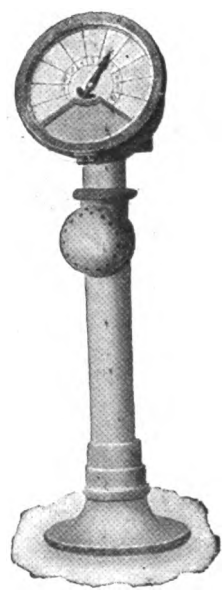

FIG. 5.—SIEMENS DIAL RECEIVING INSTRUMENT.

Each pointer is actuated by a small motor which, during the transmission of an order, receives current and is excited by means of the controller-switch actuated by the handle of the transmitting instrument. The bell fitted to each instrument can be employed, in accordance with the system of connections, either to draw attention to an order or to give a bell signal corresponding with the transmitted order. In the first case the bells ring continuously so long as the handle is turned; in the second case, however, every movement of the handle or each step forward of the pointer by one section of the dial produces a sharply defined bell signal or, if single-stroke bells are employed, a single stroke on the bell; so that the transmitted order can be understood, not only by the position of the pointer, but by the number of bell signals or strokes respectively. This double method of transmitting signals offers, it is claimed, the greatest security in working; it is, however, necessary always to start from the zero section of the dial, as otherwise the number of bell strokes would not coincide with the numbers on the corresponding sections of the dial.

Before sending a fresh order, therefore, the pointers must first be put back to zero by turning the handle of the transmitter to the left and at the same time depressing a switch next to the handle, which causes the bells to be short-circuited so as to prevent them from ringing and thereby causing misunderstandings.

It is impossible to avoid depressing this switch, because, when it is in the normal position, the transmitter handle cannot be turned to the left.

Should the installation consist of two signalling stations only an apparatus with reply-signalling device can be used. This apparatus is fitted with a red and a black pointer; the former is coupled mechanically with the transmitting handle, while the latter is actuated by the electro-magnetic movement. To transmit an order, the red pointer of the transmitter is set by turning the handle to the correct section of the dial, whereupon the black pointer of the receiver takes up its position on the corresponding section. In order to send a reply, the red pointer on the receiver is set over the black pointer, whereupon the black pointer on the transmitter moves under the red pointer. The person who gives the order is therefore assured of the fact that his order has been transmitted and received correctly.

A four-core cable is required for instruments without reply gear, but for those with reply gear a seven-core cable is necessary. The number of different signals that can be transmitted is entirely independent of the number of cores in the cable. Primary or secondary batteries can be employed as the source of current, the apparatus being worked on the open-circuit system. Should a continuous-current plant be available, the signalling current can be taken from this by interposing a suitable series resistance.

The apparatus is of simple and substantial construction in all its parts and is water and gas-tight, so that it is quite suitable for use in mines. As a proof of the efficiency of the system, we may mention that it has been used largely for over 10 years not only in many mines and other industrial concerns, but also on railways and for the transmission of all kinds of signals.

The "Adnil" Automatic Shaft Signalling System.

An interesting apparatus which has been designed to assist in the safe operation of shafts is that invented by the Deutsch Telephonwerke of Berlin, for whom the Adnil Electric Co. are sole agents. For giving signals for winding men and materials this automatic system is claimed to be perfectly "fool-proof."

The equipment for each seam comprises a combined transmitter and receiver (Fig. 1) and a single stroke bell or electric hooter. The combined transmitter and receiver is furnished with a dial over which moves a pointer, a signalling lever, "level" or "seam" indicator push, an emergency push and "level" or "seam" indicator. At the heapstead is installed a dial instrument similar to Fig. 1, but fitted with a further contact maker called the "carry out" push. A single stroke bell or electric hooter is provided for ordinary signals and a trembling bell for emergency signals.

The engine driver is supplied with receiving apparatus as shown in Fig. 2. The central switching mechanism, for setting up and automatically passing on the signals to the engine man, is contained in a small oak case having a glass front. This apparatus can be installed in some suitable situation in the engine-room. If a signal is to be transmitted by the miner at say No. 1 level, he would first of all cause the words "No. 2 Level" to appear behind the small pane in the upper part of the receiving instrument. This is done by depressing the level indicator push. At each depression the level indicators of *all* the instruments step round and display the words "No. 1 Level," "No. 2 Level," "No. 3 Level," or "Bank," as the case may be.

Digitized by Google

The stepping round of the level indicator causes an alarm bell inside the apparatus to ring. The bankman and engine driver will thus understand that all signals are to come from the level indicated as all the intermediate instruments are cut out of circuit, so far at least as the giving of ordinary signals is concerned.

The miner now moves forward his signalling lever. For every forward movement of the lever the pointer of all the instruments, excepting the engine driver's, makes one step forward and the single stroke bells or hooters sound once at every step. The signal thus given is stored up in the central switching mechanism until the bankman depresses once only his "carry out" push when the pointer of the engine driver's instrument immediately flies back to the zero position and then automatically steps round to the original signal given by the miner. The single stroke bell or hooter will also sound a number of times corresponding to the steps made by the pointer. As the pointer of the engine man's instrument steps round to the desired signal the pointers on all the other instruments return automatically to the normal position unaccompanied by any audible signal. It may be stated that the signalling

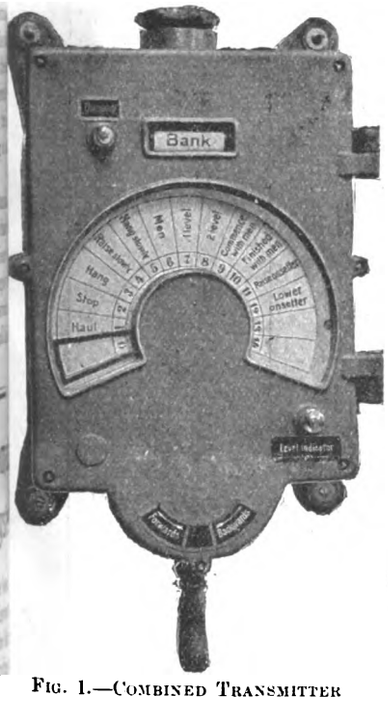

FIG. 1.—COMBINED TRANSMITTER AND RECEIVER.

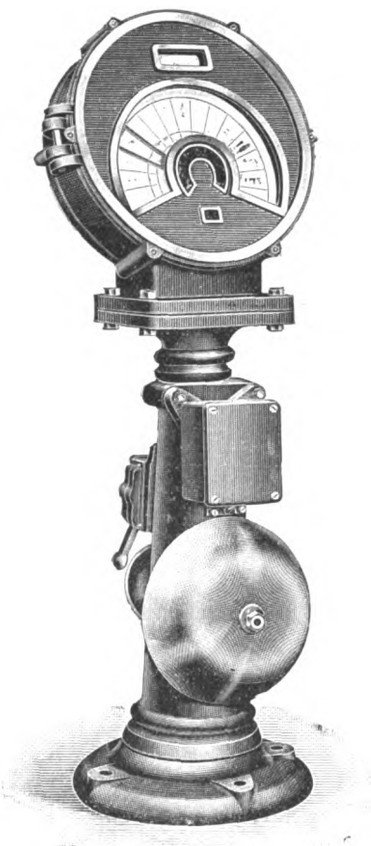

FIG. 2.—ENGINE DRIVER'S RECEIVING APPARATUS.

lever and pointer can be moved either forward or backward, but no matter how it is shifted about the engine driver receives only the signal on which the pointer is resting when the bankman presses the "carry out" push. The signal last given remains on the engine driver's instrument until a fresh signal is sent through by the bankman. The emergency push and bell is provided for use in case of danger or accident.

In addition to the apparatus above described, the "Adnil" system is sometimes fitted with a device for keeping a constant record of the last six signals given to the engine man and it can also be fitted with printing mechanism for recording the number of each signal and the time it was given. We are informed that this system is very popular in Germany and has been installed in over twenty mines, including several controlled by the German Government. We also understand that the Adnil Electric Co. have received an order to equip the William's shaft of the Dolgoath mine with this system of signalling. Copper ore is drawn from this shaft which is in Cornwall and is said to be one of the deepest in the world.

A High-Tension Telephone.

An interesting instrument which has been designed by Messrs. Siemens Bros. & Co. for use on telephone lines, running in proximity to high-tension circuits, thus often enabling one pole to be used for both high tension and telephone lines is the high-tension telephone illustrated in the accompanying photographs

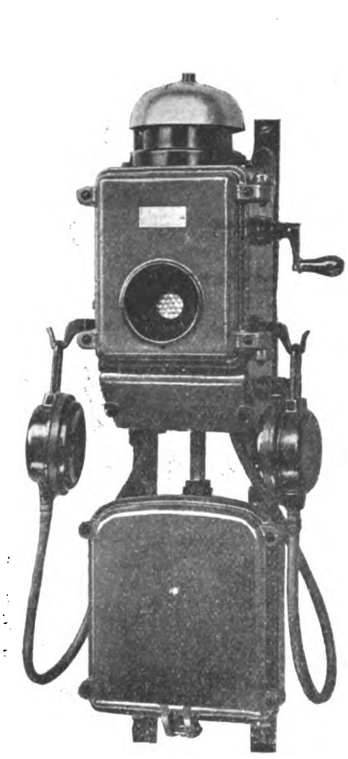

FIG. 1.—GENERAL VIEW OF HIGH-TENSION TELEPHONE.

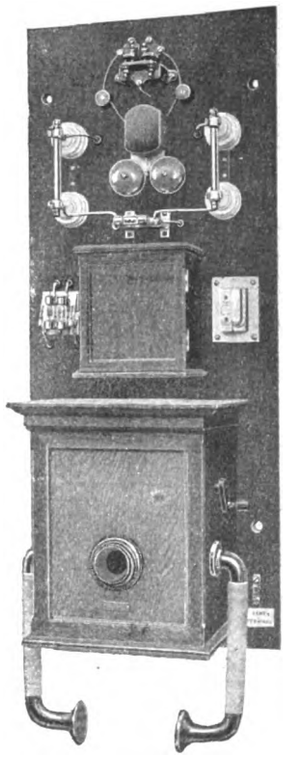

FIG. 2.—VIEW OF PROTECTIVE APPARATUS.

(Figs. 1 and 2). This instrument, which is of the "bridging" type and can be used therefore as a terminal station or "bridged" across the line, is fitted with the latest most sensitive and efficient protective devices for ensuring the safety of both user and instrument. The telephone itself is so arranged that the user is not brought into contact with any current-carrying part of it, the sound being transmitted by means of insulated hearing tubes. Fig. 3 shows a portable type of instrument.

FIG. 3.—PORTABLE HIGH-TENSION TELEPHONE SET.

The following (Fig. 4) are details of the different protective devices, with their several uses. The lines enter at a point arrester designed to conduct heavy lightning discharges to earth; they then pass through two retardation coils which effectually bar the way to a possible residual discharge, and

Digitized by Google

continue through two high-tension non-arcing fuses which cut off the apparatus in case of a cross with a power circuit. A vacuum arrester, which is bridged across these fuses, serves to short-circuit the instrument in the event of a difference of potential arising between the lines. Each line then traverses a combined spark-gap and vacuum arrester fitted with a heat coil. These arresters, being contained in a vacuum, are so sensitive that they will actuate at 300 volts and thus afford protection against every power circuit. The heat coil comprised in this type of vacuum arrester is arranged to fuse at

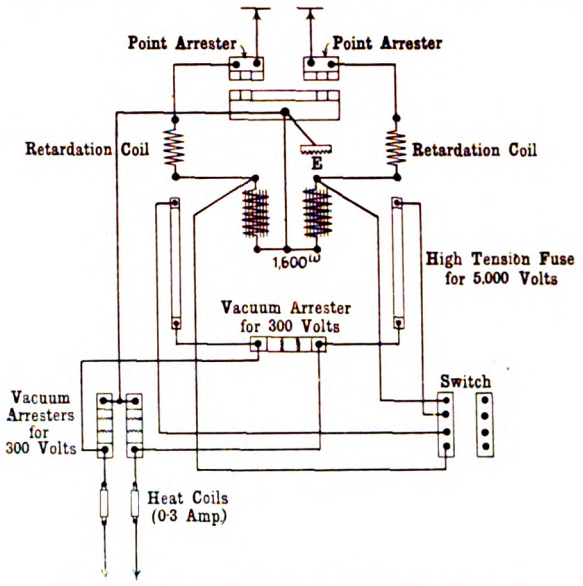

FIG. 4.—DIAGRAM OF SIEMENS H.T. TELEPHONE.

0·3 ampere, thereby protecting the instrument from "sneak" currents, which, though only small, may, by flowing for a prolonged period, do serious damage.

Sterling Mining Telephones.

In the following article we give some details of the telephones designed and manufactured by the Sterling Telephone & Electric Co. for mining work.

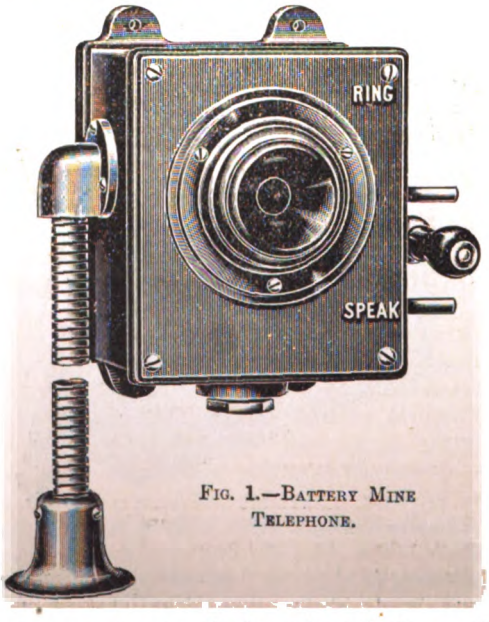

FIG. 1.—BATTERY MINE TELEPHONE.

Fig. 2 shows a magneto ringing mine telephone. It is contained in a waterproof iron case, and comprises a horizontal granular carbon transmitter fitted inside the box, an induction coil, triple-magnet generator, two double-pole receivers with cords encased in leather tubing, a 2,000-ohm polarised call bell with the movement enclosed in a waterproof iron box mounted separately on the backboard, an automatic switch hook provided with a stuffing box, backboard, and battery box of paraffined oak for two Leclanché cells.

Fig. 1 shows a battery ringing mining telephone. This is also enclosed in a waterproof iron case. It comprises a capsule "inset" shot carbon transmitter, an induction coil, a large pattern powerful double-pole receiver, a hand ringing and speaking switch, a hearing tube, and substantial connecting terminals. The whole of the above parts are fitted in a cast-iron waterproof case, provided with a stuffing gland through which the line wires are led to the interior.

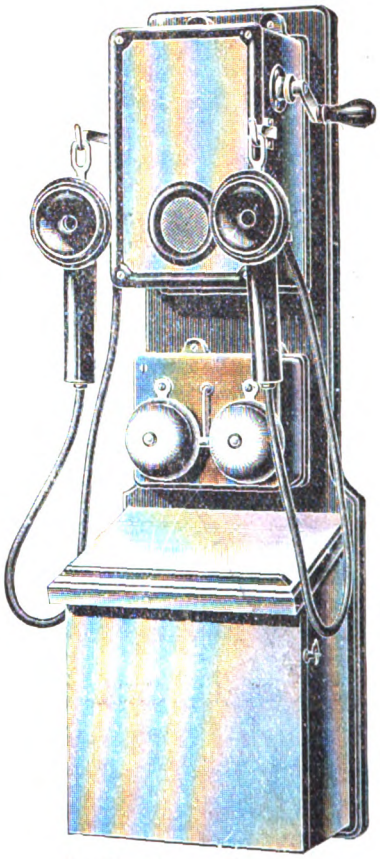

FIG. 2.—MAGNETO RINGING MINE TELEPHONE.

FIG. 3.—ANOTHER MAGNETO MINE TELEPHONE.

Another magneto instrument specially designed for use in mines is that shown in Fig. 3. It consists of a complete pole telephone for the magneto ringing type of local speaking battery systems. It comprises an aluminium damp-proof hand-combination of great mechanical strength with a loud-speaking receiver. This receiver is fitted with a leather ear-pad. There is also a loud-speaking interchangeable inset transmitter with a folding leather mouthpiece and battery key in the handle an induction coil, powerful triple-magnet generator, which is fixed on the base to facilitate removal for inspection, a large double dry cell, a carbon lightning arrester, line fuses and terminals. The whole of the parts are mounted in a solid teak case and are enclosed in a watertight iron box with a brass

Digitized by Google

lock and key and glass-fronted receptacle for emergency key. The whole set is complete with four strong wrought-iron fixing straps, bolts and nuts.

Fig. 4 shows a telephone which has been arranged for use on telephone lines which run in the neighbourhood of high-tension circuits. The receiver, transmitter and generator are

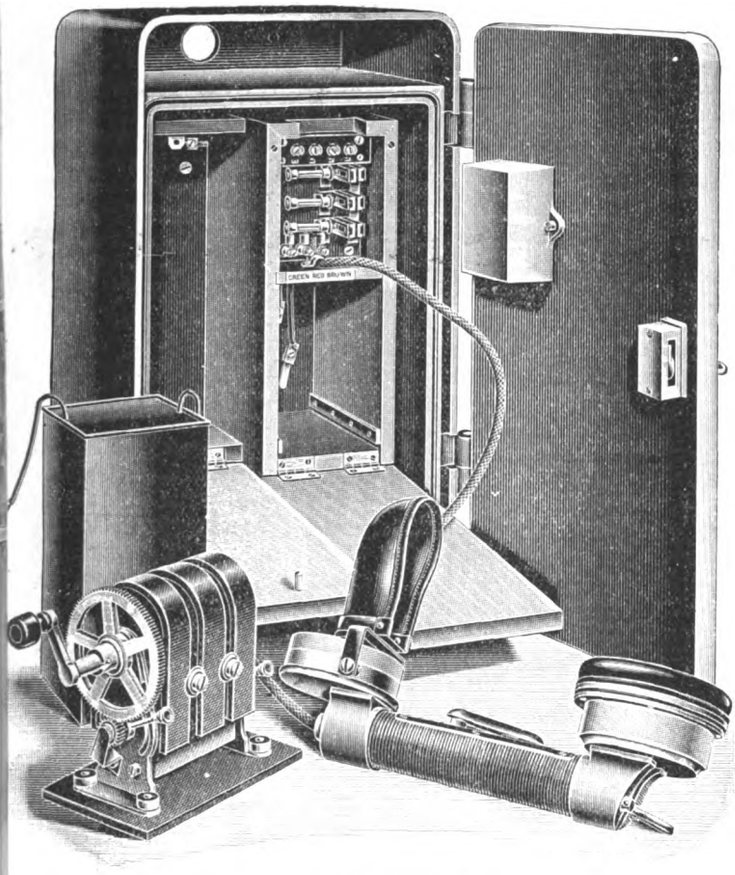

FIG. 4.—TELEPHONE FOR USE NEAR HIGH-TENSION LINES.

insulated so as to exclude completely any danger which might arise by contact between the telephone lines of high-tension conductors.

Warning Notes for Mines.

The extension of mining operations to points which, in some cases, are several miles removed from the main shafts has occasional demand for a means of giving audible warning to miners of approaching danger or for other reasons. At the same time, the extension of electric circuits in collieries and mines has been responsible for the introduction of electric warning signals and bells.

The piercing sounds emitted by such a device as the "Klaxon horn are admirably suited to give warning to miners at almost any point of the workings. The "Klaxon" horn is an extremely simple device, and it has the merit of being of substantial construction, so that it should be capable of meeting the most severe conditions in mining service. The "Klaxon" horn is well known in the motor car and motor boat world, and has, we understand, successfully withstood the most severe tests.

The horn depends for its sound on a small motor, the armature of which is placed in a vertical plane, and the upper end of its shaft is extended a matter of 6 in., and fitted at the extremity with a steel disc having a regular number of projecting teeth. These are revolved at a high rate of speed—the motor runs at 3,000 revs. per min.—and in turning they strike against a vanadium steel anvil, which is firmly secured in the centre of a thin steel diaphragm. This diaphragm is securely fixed round the circumference of the disc with an annular clamp. Fig. 1 makes this construction perfectly clear. The horn for the dispersion of the sound is placed immediately in front of the diaphragm, and it may be of any desired length according to the purpose for which the horn is required. Fig. 2 is an illustration of the complete instrument with a long pattern of horn for the transmission of sound over long distances. The motor can be operated from a battery circuit of 4 or 8 volts, but the motors can be supplied for operation on 110-volt circuits.

FIG. 1.—CONSTRUCTION OF "KLAXON" HORN.

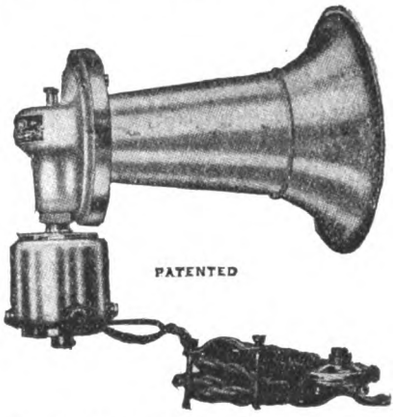

FIG. 2.—COMPLETE INSTRUMENT WITH LONG HORN.

For industrial service the "Klaxon" can be employed as a hooter for sounding the hours for the workmen. We understand that some experiments were recently carried out in the rivetting shop of a large boiler works where the fiendish din has rendered the men practically deaf. Previous to the introduction of the "Klaxon" horn it was next door to impossible to ring off the men. By the use of two "Klaxon" horns, one at each end of the shop, the men understand when it is time to go to dinner or to knock off work.

In addition to the electrically-operated pattern referred to above, a hand-worked design has been got out. Illustrations of the interior and exterior of this are given in Figs. 3 and 4.

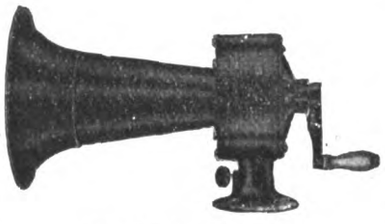

FIG. 3.—HAND WORKED HORN

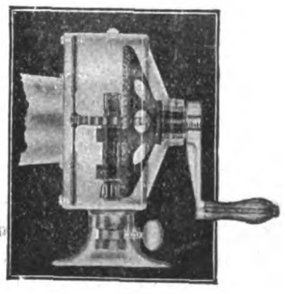

FIG. 4.—SECTION OF HAND WORKED HORN.

This is sufficiently light to be carried about and it would be found useful to take into the workings and in case of a fall or the imprisonment of the men, they would be able to give indication of their whereabouts or welfare. Further details and prices of this horn can be obtained from the Motor Accessories Co., Gt. Marlborough-street, London, W.C.

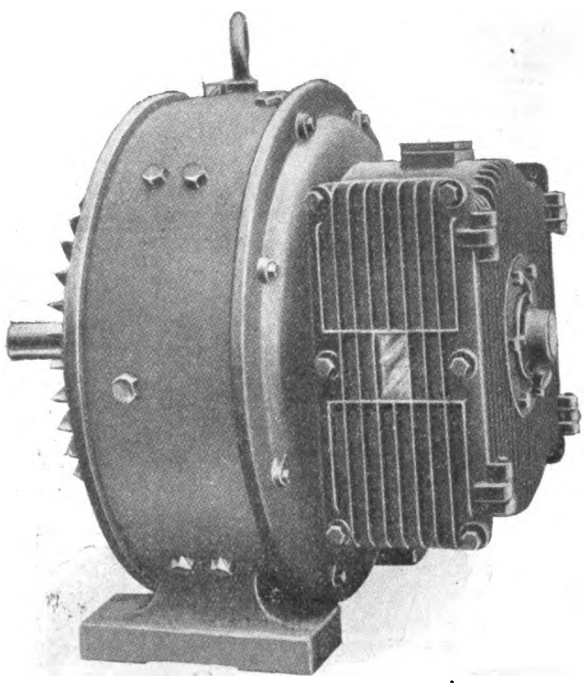
Electric Winding for Collieries.—With reference to the article dealing with the electric winding engine at South Kenmuir Colliery which appears on p. 128 of this issue, we are asked by Messrs. Crompton to state that the figures of efficiency given therein refer to the 140-fathom depth, and not to the 90-fathom depth which is at present being worked.

Digitized by Google

"Phœnix" Mining Motor.

The Phœnix Dynamo Manufacturing Co. inform us that in the ordinary course of a large business in colliery work they are repeatedly asked for a motor which shall be perfectly and permanently flame-proof under working conditions, and at the same time be simple in design and construction. In attempting to solve this problem, they realised from the beginning that the best results could only be obtained by co-operation with prospective users of such plant, and they are greatly indebted to several well-known mining engineers, whose advice was given during the period occupied by the design and experimental perfection of the new type. As a result of repeated conferences, a certain number of essential conditions was first of all laid down, and the finally completed design is shown in the accompanying illustration. They claim that this machine is undoubtedly a mining motor designed by mining men.

The following conclusions were the outcome of their investigations previous to the design of the motor :—1. The machine must be absolutely explosion-proof. The Phœnix mining motor is absolutely flame-proof under explosion pressures. Total immunity from the passage of flame is achieved by making



PHŒNIX FLAME-PROOF MOTOR.

each joint on the surface of great length. There are no oil chambers or passages, and the bearings, which are placed outside the motor proper, have no direct communication with the interior of the machine. Where the shaft passes through the casings, cooling glands are fitted, the efficacy of which glands is fully established by the tests described lower down. 2. Its working parts must be easily accessible; its doors must be easily sealed, and the brushes in the case of direct-current motors must be easily visible without breaking any seals. The Phœnix mining motor has two large doors of very adequate size for adjustments. These doors are sealed in a very simple manner so that the motor cannot be opened by any unauthorised person without it being detected. The machine is fitted with observations windows, consisting of ½ in. plate glass suitably protected. The leads are all brought out at the top of the machine and arranged in such a position as to prevent, as far as possible, damage by abrasion. 3. Its rating must be very ample to avoid overheating and its capacity for overloads great. The clearances between live parts and the carcase or castings to be very ample. The Phœnix mining motor is designed to give its full output at a specified temperature rise. Further it will give 25 per cent. overload without sparking and 50 per cent. overload without injurious sparking. The clearance between the brush holders and the carcase is unusually large. 4. Its lubrication must be automatic and require only the minimum amount of attention. If oil wells are eliminated much less attention will be necessary. The Phœnix mining motor is fitted with heavy type ball or roller bearings; the housings are perfectly (not commercially) dust-tight. There are no oil wells, and the machine will run for three months without a renewal of the grease being necessary. The bearings are of a special type, manufactured to withstand shock and are guaranteed for two years. It should be noted that the following causes of serious trouble in the usual type of machine—oil creeping and leaking, overfilling of oil chambers, and any chance of hot or "seized" bearings are totally eliminated. 5. The insulation must be moisture proof and of exceptional quality and robustness. The Phœnix mining motor is insulated by a special process; each coil is subjected to a high-pressure test—(*a*) After winding; (*b*) After fitting into the core; (*c*) On the completion of the armature. The windings are impregnated under vacuum on two separate occasions, and during the last operation they are subjected to a pressure of 50 lb. per square inch, thus assuring that all the the interstices are filled with insulating materials. No insulating material or varnish is put into the machine unless it is capable of standing, without damage, a temperature of 250° F.

A series of explosion tests has been repeatedly made on this motor in the presence of mining experts. The motor was placed inside a chamber made of heavy wood, zinc-lined, and suitable connections were made to a device for passing into the case a mixture of gas and air, previously tested by an explosion meter so as to ensure its being of the most explosive character procurable. Sparking plugs were fitted, one inside the motor itself and the other inside the case.

The motor was first lifted out of the case, filled with gas and air mixture, and exploded electrically by means of a sparking plug. After five or six similar explosions, no detrimental effect or any signs of the explosion were visible on the motor itself, thus proving, that it was quite suitable for withstanding explosion pressures. The discharged gases were then blown out of the motor, which was again filled with gas and air, and the complete machine was placed inside the wooden explosion chamber, which chamber was in turn filled with the correct mixture of gas and air. The mixture inside the motor was then fired, and the gas in the explosion chamber itself was not exploded. Then as a proof that this outside mixture was actually explosive, the sparking plug fitted therein was fired and a complete explosion followed.

The whole object of this test was to reproduce as nearly as possible the actual conditions which would obtain in a mine. It is obvious that the first time the doors were opened below ground, the motor itself would become full of the gaseous atmosphere surrounding it, so that in the case of a short circuit or spark occurring in the machine, this internal mixture would be exploded, and the claim which was established during the test described above was that in the event of this taking place in a Phœnix flame-proof motor, there could be no resultant explosion of the outside atmosphere. These tests have been frequently conducted in the presence of mine owners and experts and have been pronounced to be quite conclusive.

Miners' Safety Lamps.

For a great many years this country has been in the position of having a large proportion of its safety lamps manufactured in a haphazard manner by firms of general brass workers, who make specialities of water or steam valves or the like, filling any spare time with safety lamps; as a result of this nondescript method of manufacture, and the ignorance of the makers of the essentials of a safety lamp, there have been placed on the market a great variety of odd size lamps, many of which can be shown to be quite unsafe, either from original defects in the type of lamp or in its manufacture, or from defects brought about by

Digitized by Google

lack of standard size and consequent bad fitting of the renewals. Having made a scientific study of miners' safety lamps and appliances connected therewith, and having spent large sums of money in experiments and improvements thereon, and in the purchase of the best and most up-to-date machinery for their production, Messrs. Ackroyd & Best feel they are in a position to turn out the very best article, and to give every satisfaction under the most trying circumstances. Their lamps and apparatus are now and have been in use at some collieries for close upon 20 years, and although they have something like 200,000 lamps in use in good, bad and indifferent mines in this country, they have never yet heard of a single instance where they have been the cause of a mine gas explosion.

There is no doubt that the electrically ignited oil lamp, furnished with an automatic lock, which can only be opened by

FIG. 1.—ACKROYD & BEST MINERS' SAFETY LAMP.

an electromagnet in the lamphouse, is now considered the standard mining lamp, one reason being that with it relighting in the mine is absolutely safe, which cannot be said of lamps fitted with self-contained igniters, these latter having many objectionable features, amongst which may be mentioned the ease with which such igniter may be operated by the aid of a common nail roughened or chipped by a wedge or chisel on one side, near the end, this being readily inserted so as to catch and grip the operating spindle of the igniter of the lamp, and so easily operated by any lad or man in any part of the mine, such, for instance, as the coal face or in the comparatively dangerous return airways, and possibly a light may be formed in a lamp having a damaged glass, and, of course, if gas be about, an explosion would consequently ensue. Seeing, therefore, the ease with which this igniter may be operated in an unauthorised manner in the mine, it appears to us that a false sense of security is created by the provision of screwed special keys in the custody of the deputy, or by chaining the key to a prop some distance from the coal face. In the latter event it is highly probable the key would be stolen.

With self-contained igniter lamps, an air inlet underneath the glass is generally employed. This is, Messrs. Ackroyd & Best consider, not only mechanically bad, but it is highly probable that just at a critical moment, when the lamp is required to withstand an unusual influx of gas, the gas flame which would burn at this inlet would so heat the glass that it would crack, and the mine gas be ignited and an explosion ensue; furthermore, highly volatile spirit is generally used in these lamps, and their experience is that there is a general movement taking place to cast out spirit lamps owing to the risk in the mine and also on the surface of burning down the lamp cabin and the whole pit head gear. They have, therefore, concentrated their attention more and more on high-flash oil lamps and apparatus. It is impossible to open the lamps with the means available to a miner in the mine, and it is only possible to relight them at the safe relighting machines fixed at convenient positions in the pit, the relighting machines being too heavy to be moved surreptitiously from the position

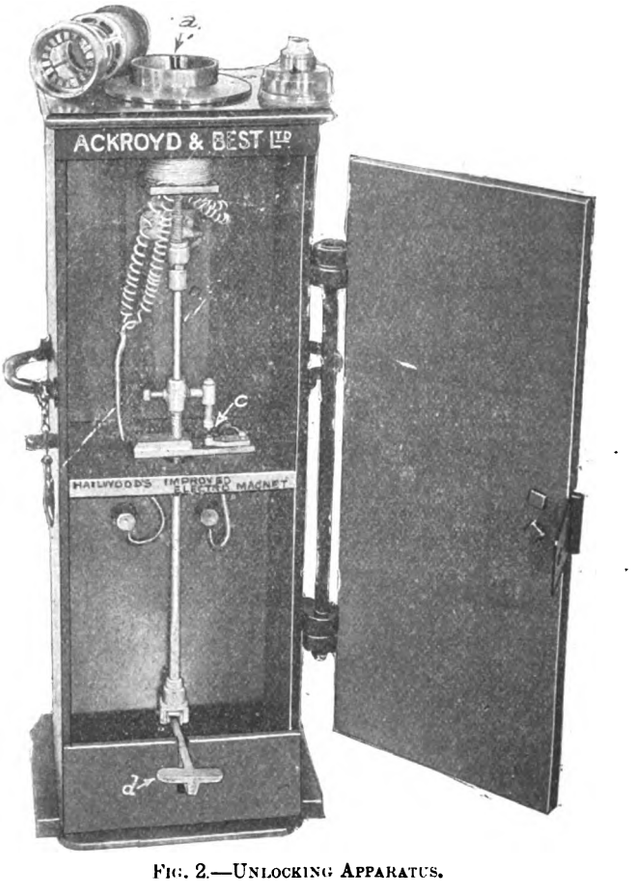


FIG. 2.—UNLOCKING APPARATUS.

assigned them by the officials, and yet not too heavy to prevent their being moved forward by the proper authorities as the coal face advances.

Under the Ackroyd & Best system, the miner receives a perfectly clean lamp which is only lighted when called for by him, and has not had to stand burning for hours on the lamp-stand, as is the case with the old style of lamps, which are lit by a torch and then locked, necessitating the commencement of the lighting-up process hours before the miners arrive. If the light goes out in the mine, it may be quickly and safely recovered on one of the safety underground relighters, which are placed at convenient positions in the pit. The miner, therefore, has no incentive to open his lamp, but if he should have such a desire he is faced with the insurmountable barrier, *i.e.*, the magnetic lock.

With these lamps and apparatus the lampmen, it is claimed, are able to do their work well and quickly, because all the parts

Digitized by Google

of the lamp are so arranged as to enable the cleaners to manipulate them in the least possible time. A special feature of this lamp is that if the gauze be absent the lock at once demonstrates the fact by refusing to act, so that it is unlikely a lamp can be sent into the mine without being provided with a gauze. This, Messrs. Ackroyd & Best submit, is far better than the employment of a detector in the bonnet, seeing the latter invariably gets dented, thus preventing the detector acting.

The magnetic lock described below has withstood the severest possible tests, and it has been proved to be impossible for anyone to make it fail or to tamper successfully with it in the mine.

The lamp shown in Fig. 1 is fitted with Ackroyd & Best's patent glass ring and oil filling valve, and Hailwood's patent automatic magnetic lock, combined electric igniting pin, wick snuffer, and removable wick tube. The vessel is cast in one piece, thus doing away with the soldered bottom plate. Platinum is not used in the lamp. All the parts are simple and strong, the bonnet is formed of one piece of seamless and jointless steel, the crown being an additional plate for extra safety. The lamp burns oil having a flash point of over 250°F., and is very sensitive to gas.

Fig. 3 illustrates the lamp in which part of the vessel and bush have been cut away so as to show the interior of the Hailwood patent lock; it will be seen that the glass-holding ring *a* is provided on the underside with ratchet teeth into which engages the iron lock bolt *b*, which is held in the up position by means of a strong spring *d* resting on a slidable iron guard plug, *e*; the latter resting on a solid shoulder formed in a recess in the lamp bottom. This guard plug effectively prevents any tampering with the lock. Anyone pressing the guard upwards compresses the spring *d*, and causes it to hold up the lock bolt *b* even more effectively, making it impossible to tamper with the lock by means of a permanent magnet, whereas, when the lamp is placed on the electromagnet described below, the nose of the magnet will press upwards the guard plug *e*, magnetise it, and get a strong magnetic grip of the lock bolt *b* immediately the plug comes into contact with it. The depression of the electromagnet pedal drawing down the guard plug, and with it the lock bolt *b*, thereby releases it from the teeth of the glass ring, so that the lamp top may be unscrewed from the oil vessel, all of which is the work of only a moment. To lock the lamp, the mere act of screwing on the vessel will cause the lock bolt *b* to click over the ratchet teeth of the glass ring until the oil vessel has been screwed home, and the vessel then cannot be again removed until opened by the electromagnet.

Particular attention may be drawn to the fact that all the lock parts are inserted from the upper face of the lamp vessel, and are held in position by a detachable screwed bush, *c*, so that if at any time it is desired by the surface officials to take out and renew the lock parts, this operation may be performed in a moment, as there are no pins to drill, out and unsolder and to re-solder. A further most important point is that if dirt should wash down into the lock it will not interfere with the opening of the lock in the lamp-house because the nose of the magnet presses the guard plug up and squeezes out any dirt, thus getting a strong magnetic grip of the lock bolt *b*. This enables the strongest possible spring to be employed. It will be obvious that this method is far superior to that in which the guard plug is inserted from the bottom of the vessel, and is secured in position by a screwed and soldered pin, which may be surreptitiously forced out, the lock parts abstracted and the lamp opened. This latter type of lock (and, in fact, most locks intended to be opened by a hand or permanent magnet) is also subject to the great objection that the lock bolt is attracted to the plug through an air gap. It will, therefore, be seen that it is only possible to employ a very weak spring with such locks, and this in course of time allows the lock bolt to lag or stick in the open position. And again, when dirt washes down into the lock parts in the lock in question, the dirt effectively prevents the magnetism penetrating it and drawing the lock bolt down. The result is that the only way in the cabin to open such a lamp is to break it or drill out the lock, thereby creating confusion and delay in the lamp-house. On the other hand, lads of 14 or 15 years of age can open these lamps on the electromagnet in the lamp-house as fast as lamps can be handed to them, and at a rate quicker than the old lead plug locks can be knocked off.

The illuminating power of this lamp in English standard candles is 0·67, as compared with 0·71 standard candle power of the ordinary tallow dip candle, and 0·66, the highest standard candle-power of the open flame lamp burning seal oil (the height of flame in the open lamp does not continue long, for rapidly decreases).

The absence of means for completely snuffing the wick of a lamp during a shift has long been recognised as a great grievance; this trouble was particularly acute with the electrically-ignited oil lamp, because of the difficulty in getting the current to penetrate the hard crust which formed on the top of the wick of an extinguished lamp, this crust often preventing the relighting of the lamp in the mine. Hailwood's patent snuffer provides, it is claimed, a simple remedy for a long-felt want. An insulated brass wire which passes through the lamp vessel is provided at its upper end with a cross-head, one end of which acts as a sparking point for throwing on to the wick the electric spark which ignites it, whilst the other end of the cross-head is thinned out so as to form a snuffer arm. When the igniting point is in position the snuffer arm is directed away from the burner, and therefore cannot interfere with the igniting process, as would be the case if the snuffer was on a separate pin. The bottom end of the brass wire is provided with a brass button, between which and the underside of the lamp vessel is

FIG. 3.—LAMP CUT AWAY TO SHOW PATENT LOCK.

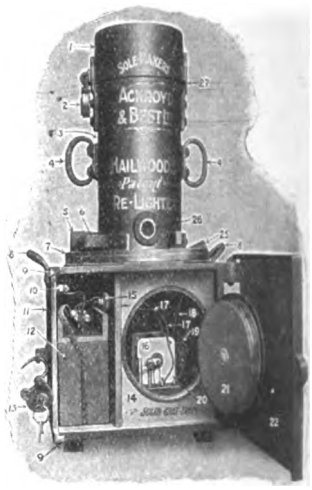

FIG. 4.—UNDERGROUND RELIGHTING APPARATUS.

a small spiral spring, tending to keep the igniting pin and snuffer depressed below the height of the flame, so as to avoid forming shadows. In the centre of the porcelain part of the burner a nick is formed, into which the igniting pin falls when the above-mentioned button is operated, and thus ensures the lighting pin always being in the best position for relighting.

For unlocking, the lamp is placed in a brass dish on the top of the apparatus (Fig. 2), the lock of the lamp being over the magnet rod *a*. The foot-treadle *d* is then depressed, thereby closing the switch *c* and simultaneously causing the current to flow round the coil, this transforming the iron core rod into a powerful magnet, which seizes hold of the lock-bolt. The continued depression of the treadle and magnet core rod withdraws the lock of the lamp, so that the latter may be opened, the whole operation being the work of an instant. These machines are simple and strong and unlikely to get out of order, cast or wrought iron being employed in the construction of the box and door portions.

The underground relighting apparatus consists essentially of a large rectangular iron box 11 (Fig. 4), having a subsidiary chamber, 14, cast solid with it. This latter chamber carries the induction coil 16. The coil chamber is closed by a circular door, 21, having a flange 1¼ in. deep, which is provided with screw threads over its entire surface, and which engages with

Digitized by Google

similar threads provided on the circular aperture in chamber 14, so that when the door is closed it automatically makes a gas-tight joint, which cannot get out of order. This circular door is firmly hinged to the side of the box 11. It cannot be misplaced, it is claimed, and must, in fact, be closed completely before the flat door 22 can be closed and padlocked. Accumulators are placed in a compartment of box 11. To allow of the easy escape of the small quantity of accumulator gas which may form, ventilation gaps 9 are formed between the front of box 11 and the inside of the flat door 22, the flange of which door guards the gaps. On the top of the box 11 is placed the lamp chamber formed of two iron cylinders, the outer one 3 being capable of revolving round the fixed inner one 30. In the base of the fixed inner cylinder an iron lamp dish having an insulated electric contact is arranged. Lamp admission openings are formed in the walls of the two cylinders. To enable the lamp to be passed into the inner chamber the outer cylinder is revolved until the opening in it coincides with the opening of the inner cylinder, the lamp being then completely enclosed by the reverse rotation of the outer cylinder, somewhat after the manner of the well-known policeman's lamp. Above the crown of the lamp chamber is a further chamber, which, when all the parts are assembled, is closed in by a deep iron cap. In this latter chamber is arranged a switch device in such a manner that the lamp chamber must be closed before the current can be switched through the lamp, and also that the lamp must be in position before the electric circuit can be closed. The current from the accumulators and the induction coil is conveyed by a cable to the switch chamber through steel tubes in the walls of the inner lamp chamber, and terminate in a protected terminal. Directly above the terminal there is arranged a spring contact carried by a push bracket. The upper end of the contact is in electrical connection by means of the flexible cable with a spring contact plunger push carried by the push bracket. The lowest end of the push is directly over a corresponding aperture in the crown of the lamp chamber. This latter push is also provided with a steel roller, supported on the upper face of a circular steel cam plate attached to the upper part of the cylinder. When the lamp chamber is open the roller and push bracket are kept in the upper position, and the circuit is consequently broken. But as the outer chamber is revolved into the closed position the roller will descend and cause the contacts to engage. Current then passes to the spring contact plunger, which latter will, on its descent, penetrate into the lamp chamber and come into contact with the lamp placed therein, the current being conveyed through the lamp to the vicinity of the wick tube, while sparking across the wick effects the ignition. It then passes to the insulated contact in the base of the lamp chamber and back to the induction coil and accumulators. When the lamp chamber doors are open an iron guard plate connected to the outer chamber lies in front of the aperture through which spring contact push enters the lamp chamber, and this guard plate automatically moves clear of the push as the lamp chamber is closed. So that whilst the lamp chamber is open it is impossible to tamper with the electric circuit.

The machine is also provided with a device which ensures that only a safety lamp may be placed in the lamp chamber. The lamp chamber can be locked by a spring lock operated by a peculiarly shaped left-hand threaded key, which may be placed in the care of some person or persons in the respective districts of the mine, although from this description of the apparatus it will be obvious that even if this chamber be left unlocked no harm can result, as the lamp must be in its position and the chamber closed before any electric current can be caused to flow, and in this position the man can do no tampering with it. The switch chamber is closed in by a cap, 1, provided with a strong padlock, 2, which is a duplicate of the padlock 13 of the accumulator chamber, the keys of which are in the care of the lampman or some other official appointed for the purpose. A buffer, 5, and buffer block, 6, are provided to reduce the force of a too violent rotation of the chamber 3.

The operation of relighting a lamp is very simple, as it is only necessary to insert it into the lamp chamber and rotate the outer cylinder, which automatically encloses the lamp and automatically causes the switch to close on the lamp, and the electric current to ignite it, and this without having opened the lamp, the whole operation being only the work of a moment, while every function of the apparatus must invariably follow in its correct sequence from the simple rotation of the outer cylinder. The wearing parts are made of steel, and all joints are either automatically gas-tight, as in the coil chamber, or automatically flame-tight, as in the lamp chamber and switch chamber.

A combined lamp (the Allott, Hailwood & Dean) has been specially designed by Messrs. Ackroyd & Best to suit the requirements of officials and firemen. It combines not only a ready means for testing for firedamp—viz., the standard oil flame—but is also provided with a powerful electric incandescent lamp, the light from which enables a critical examination of the roof to be made. In the event of a disaster in the mine it is possible that the person provided with such a lamp might survive the first effects of the explosion, and if so he would no doubt be able by means of the electric light to reach a place of safety and assist other survivors likewise. In everyday use in the mine he would find this electric lamp useful in reaching a re-lighting station if he should have the misfortune to lose his oil flame light.

In this lamp a long tube-like oil container is surrounded by an annular accumulator in a case, the negative terminal being connected to the case, whilst the other terminal is secured to a plate to which a terminal is attached. The oil container is provided with a shoulder having an insulated contact roller connected to one terminal of a small electric incandescent lamp. The oil container is placed in a circular recess formed by the inner wall of the accumulator, the square base of the oil vessel entering a similar opening in a base plate in connection with a revolvable flange loosely attached to the accumulator case. When it is desired to employ the electric light, say, for instance, if the oil light has been lost, or as an additional light for inspection of the roof, &c., the flange is rotated until roller of the electric lamp rests on the contact plate. The circuit is then completed. The light may be quickly cut out by simply rotating the flange in the opposite direction. When recharging the accumulator with current the wires of the generator are connected to terminals on the base of the lamp. This lamp is very compact and strong, and all the parts are easily accessible to the lamp cleaner.

A Machine which Uses Pit Rubbish as Fuel.

A study of British collieries brings into prominence many important and interesting features in their conduct and management. One of the most interesting of these is the way in which economy may be obtained by the installation of efficient and suitable machinery and labour-saving devices. Yet, often there remains at least one department of the British colliery that is not as efficiently equipped as it should be if the best commercial results are to be obtained. This is the more surprising, for full credit may be accorded to its indispensability. The department indicated is that containing the steam raising plant.

It is not unusual, Messrs. Bennis & Co. inform us, for those responsible for colliery management willingly to expend a considerable sum on the purchase of boilers and engines of the type judged most suitable for the work to be accomplished, and yet to hesitate and haggle over the price of machines for boiler firing, although the use of such machines leads to an extension in the boiler life, and increases the output of steam. At many of the leading collieries the whole of the coal used in hand-firing the furnaces is of considerable market value, and might yield no mean profit if added to the year's sales, instead of which it is withdrawn from possible markets and used in the manufacture of the requisite steam for consumption by the colliery.

Digitized by Google

Were there no alternative there could, of course, be no objection so to employ a marketable commodity, but there is an obvious alternative in using pit rubbish and other unmarketable stuff by the means of adequately designed machine stokers. This being the case, it seems extraordinary that such machines should be ignored. In collieries sufficiently wide-awake to have made the substitution, the results obtained by adopting such equipment have been extremely encouraging.

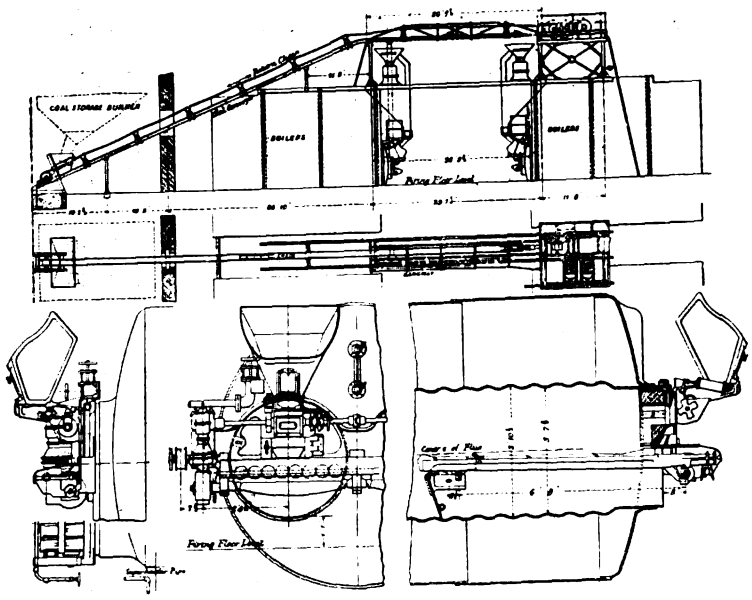

FIG. 1.—"BENNIS" CONVEYOR PLANT AND MACHINE STOKERS INSTALLED IN A CONTINENTAL BOILER HOUSE.

It may not, therefore, be altogether devoid of interest in this connection if we here record a few facts pertaining to boiler houses where this system of boiler-firing is in vogue. These particulars have been kindly supplied by Messrs. Ed. Bennis & Co. In three of the best-known collieries in Yorkshire, whose increase in profits are the envy of others, the ranges of Lancashire boilers are fired by means of "Bennis" machine

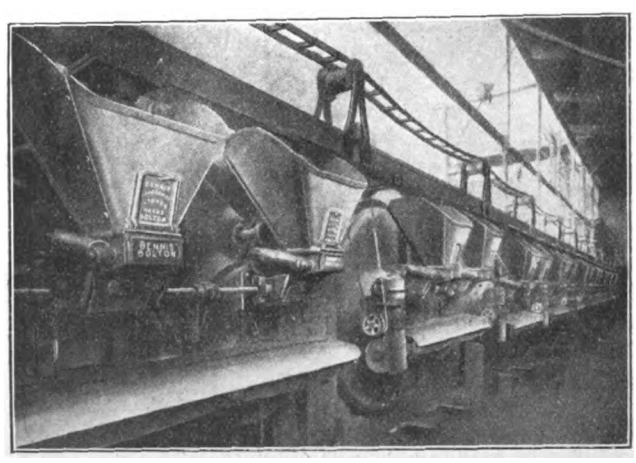

FIG. 2.—A "BENNIS" U-LINK CHAIN CONVEYOR DISTRIBUTING COAL INTO THE HOPPERS OF THE "BENNIS" MACHINE STOKERS AND SELF-CLEANING COMPRESSED AIR FURNACES INSTALLED IN THE BOILER HOUSE OF ONE OF THE BEST KNOWN COLLIERY COMPANIES IN THE WORLD.

stokers and self-cleaning compressed air furnaces. It is generally admitted that for colliery purposes no boiler is superior to the Lancashire type; owing to its hard driving capacity, low costs for repairs and long life, the Lancashire boiler of 8 ft. by 9 ft. diameter is difficult to surpass. These boilers can be made with flanged dished ends so that the tubes may be renewed without the removal of the end-plate. The evaporation of a Lancashire boiler when hand-fired with fairly good coal may be from 7 lb. to 9 lb. of water per lb. of coal, whereas when fired with pit rubbish by means of a "Bennis" machine the evaporation, we are informed, is increased by 25 to 35 per cent.—a very good result, it will be agreed, from material that under ordinary conditions it is necessary to pay to remove as waste.

Nor is the increased evaporation by means of unmarketable refuse the only advantage which Messrs. Bennis find is due to the substitution of machine stoking for hand firing with costly fuels. The boiler life is considerably increased owing to the fact that it is not necessary to open the fire doors, an operation which admits draughts of cold air, thus causing sudden contraction of the boiler front as well as the rapid cooling down of the steam. The machines are fed automatically, without the opening and shutting of the fire doors, by means of an adjustable spring which scatters the fuel on the fire where it is required with a nicety that almost amounts to intelligence. Nor is it requisite that expensive manual labour should be constantly employed in feeding the machines or bringing the coal from remote parts of the colliery to the boiler house. On the contrary, all this is done by a well-designed system of elevating and conveying plant. By means of this mechanical distribution the rubbish is brought from that part of the colliery where it is collected and conveyed thence, elevated and distributed into

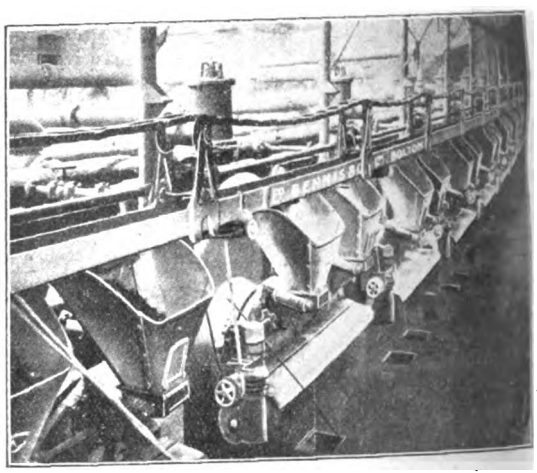

FIG. 3.—A RANGE OF "BENNIS" STOKERS INSTALLED IN THE BOILER HOUSE OF A LEADING SOUTH WALES STEAM COAL COLLIERY COMPANY.

the stoker hoppers by delivery shoots, the cost working out at a figure that is expressed by a decimal of a penny per ton. Such a system it is claimed pays for itself again and yet again within a brief period of its erection. Our illustrations show examples of Bennis equipment suitable for these.

The "Niphan" Couplings and Plugs for Electric Cables.

An interesting arrangement for connecting cables together is that known as the "Niphan." It is due to Messrs. Simmonds Bros. and consists of twin cables with rubber insulation. These cables are enclosed in flexible steel tubes or are armoured in the ordinary way. Suitable lengths of this cable can then be made up and connected together by means of a special mechanical coupling, so that any length of run can thereby be obtained.

The tubing forms, with the couplings, a continuous metallic armouring easily connected to earth, so that accidental shock is practically impossible, and it is thus quite suitable for use in mining. The most important feature of the system is the coup-

Digitized by Google

ling (Fig. 1.) The case is of brass, in two parts connected by a screwed and milled ring. The insulating material is ebonite, and the plugs are of gun-metal. Each socket is provided with a small tapered pin which enters a hole in the plug, which is split, thus spreading out the latter when home, and pressing it against the sides of the interior of the socket hole. This ensures, it is claimed, an increased area of contact, and consequently an enhanced carrying capacity. Occasionally it is desired to wire lamps in series, and for this purpose a series connector can be inserted between the two halves of the coupling, or a series coupling used.

Fig. 2 shows an ironclad double-pole fuse board fitted on the top with sockets for connecting to the circuits and a terminal at side for earthing the armouring. The large coupling at the bottom is for the mains. This arrangement is very simple for fitting up or removing, and can be fixed in a few minutes. For works, buildings, shipyards, temporary buildings, field plants and mines a strong coupling is essential to stand the rough usage they would be subjected to, and the patterns which are made with the screw-on sides and water-tight packing ring will fulfil, the

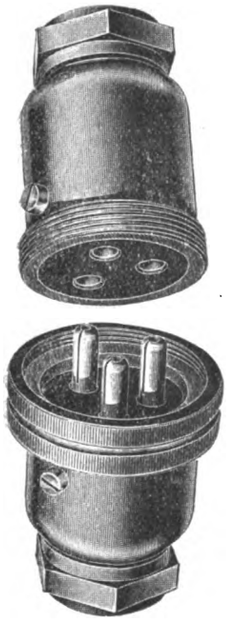

FIG. 1.—"NIPHAN" COUPLING.

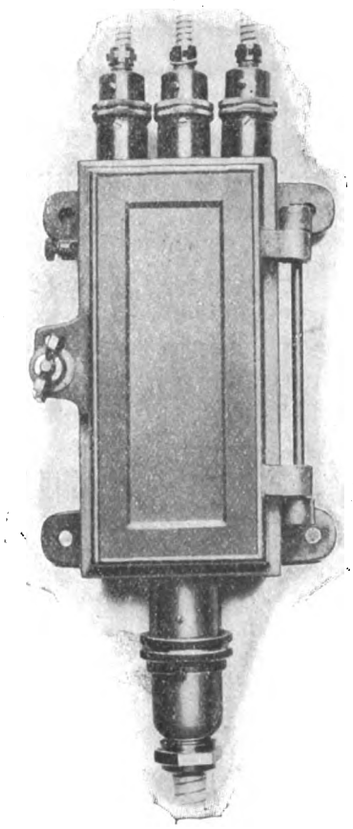

FIG. 2.—PORTABLE FUSEBOARD.

maker claims, any conditions required. For lighting circuits 8 yd. lengths of 60/30 flex in ⅜ in. tube are found the most suitable, with tappings in smaller sizes 10 to 14 yd. long, attached direct to the fittings.

The plug shown in Fig. 1 is made in cast brass with steel bronze finish and ebonite interiors. They are fitted with turned brass terminals and plugs made in one piece with steel set screws. Rubber washers are fixed on the end of the plug couplings, as well as glands for gripping cables or tubes. Plugs with a capacity of 50 amperes and upwards have spokes of unequal size to prevent reversal and the socket holes are sunk. The three-pole in all sizes are unequally spaced and can only be put together in one way. In the 15-ampere couplings, the plugs are of equal size and fit the ordinary simplex and Lundberg wall sockets. Cables enter straight into the terminals without bending.

Influence of Cut Double Helical Gearing on the Design of Electrically-driven Mining Machinery.

BY B. WIESENGRUND, PH.D., A.M.I.E.E.

In a general survey of the application of electric drives to mining machinery it is impossible to overlook the influence exercised on designs during the last few years by the introduction of machine cut double helical gearing. When electric driving was introduced into mines it was quite customary to adapt mining machinery, such as winders, underground haulages, pumps, ventilating fans, coal washing machinery, screening plant, &c., to the drive from electric motors by simply increasing the number of gear trains until a normal motor speed was reached. With this method it was not at all unusual to find slow running machines with three, or even with four, trains of gears, and sometimes a belt or rope drive in addition. It was soon felt that this method was not desirable; the large number of intermediate gears between working machine and motor not only reduced the efficiency, but it also introduced a large number of additional wearing parts and possible sources of breakdowns. Further, it was impossible to make such arrangements compact, so that, particularly for underground work, additional expense had to be incurred to provide the necessary accommodation. As the necessity for simplification became more and more apparent to manufacturing engineers and mine managers, various types of reducing gears were tried, with varying degrees of success. Some five or six years ago the totally enclosed worm reduction gear, the manufacture of which had attained a fairly high degree of perfection, came into favour, and was adopted by a number of firms both for the drive of haulage gears and pumps. The results obtained were far from uniform: whilst in a number of instances such gears proved very satisfactory, in others, particularly in those in which it was attempted to reduce the cost by using comparatively small gears, they proved costly failures. It is now generally understood that for low final speeds worm gears are not suitable, unless made in dimensions, which, both from the point of view of space required and first cost, cannot be regarded as commercial.

A great change was gradually brought about after machine cut double helical spur gearing, made from solid blanks, became available. This type of gearing admits of ratios in a single train which particularly well meet the requirements of electrically-driven mining machinery. Whilst, as recently as five years ago, a gear ratio of six or seven to one was regarded as the upper limit for spur gearing for large powers, it has been found practicable, with the double helical system, to effect much larger ratios in a single train, without any limitation in the power to be transmitted.

The explanation of the high ratio possibilities of double helical gearing is to be found in the continuity of the engagement obtained with spiral teeth. The engagement conditions of double helical teeth are such that the strains set up in the teeth are much smaller than in straight teeth; consequently, for a given power at a given speed, much finer pitches can be employed. With fine pitches it is always possible, by merely choosing a suitable face width, to bring two, three or more of the spiral teeth into simultaneous contact. The pinion diameter for double helical gears is, therefore, determined by the necessary shaft diameter to transmit the power; the pitch diameter of the pinion merely being so much larger than the shaft diameter that the root diameter of the pinion does not become smaller than the shaft diameter, the pinion being cut on its own shaft; *e.g.*, a pinion to transmit 100 H.P. at 400 revs. per min. can be made with a pitch circle of 3¾ in., and, therefore, for a ratio of 20 to 1 a wheel with a pitch diameter of 75 in. is required. This gives a final speed of 20 revs. per min., such as is frequently required for haulage gears. A haulage in which such a gear is used is reduced to the smallest possible number of parts, whilst the reduction gear itself gives the highest possible efficiency, and is more reliable than an ordinary spur gear of smaller ratio, owing to the load being distributed over a large number of teeth in simultaneous engagement, so that no single tooth of the gear has to meet shocks or hammer blows, under which straight cut gearing suffers so severely in mining machinery, which has to be started and stopped quickly and frequently.

A ratio of 20 to 1 is by no means a limit for this type of gear, the possible ratio being in each instance determined by the largest wheel which can be conveniently accommodated. Such high ratio gears doubtlessly call for a pinion material which has a high resistance against wear, not because the load on the pinion is particularly heavy, but on account of the larger number of engagements of each individual tooth. The manufacture of alloyed steels has, however, made such rapid progress during recent years, that no difficulty is experienced in obtaining thoroughly satisfactory pinion material.

The continuity of engagement in accurately cut double helical gears renders them sufficiently silent for mining work, that there is no longer any necessity, or even justification, for the use of soft pinion materials, such as raw hide, fibre or compressed paper, which with straight cut gears have been employed to reduce the very objectionable noise.

By the extensive use of high ratio gears, as described, the design of mining machinery has been changed in a marked manner. Drum haulages, with drum speeds as low as 20 revs. per min., are now regularly and almost universally made by all haulage gear manufacturers with single trains of gearing, where double and treble trains used to be employed. The same effect is noticeable in a marked degree with the design of pumping machinery, with the result that efficiencies have been greatly improved, and by a considerable reduction in the number of wearing parts the number of repairs has fallen off.

It is not surprising that, in view of the serious inconvenience and, in many cases, even danger, caused by the breakdown of underground machinery, mine managers approach this new departure with the utmost caution. Doubts with regard to the durability of the small pinions employed were frequently expressed. Three or four years' practice, however, has abundantly proved that such pinions not only have a very satisfactory life, but the entire absence of shocks and vibration has a very beneficial effect on the working machines, and breakages of gears, with which mine managers and engineers were only too well acquainted with straight cut gearing, have become a thing of the past. Mines which have had the most extensive experience with this class of gear do not find it at all necessary to keep spare gears in stock.

It is gratifying to notice that British engineering firms have doubtlessly led the way in making use of double helical gearing to modernize and simplify their machines. Amongst the large number of representative installations of double helical gears for mines carried out during the last few years, it is perhaps particularly noteworthy that for the electrification of existing main winders such gears have been exclusively adopted by the Rand Mines in South Africa. Although not a single breakdown of a double helical gear fitted to electric winders or haulages has come to the writer's knowledge, the application of such gears to electric main winders is making comparatively slow progress in this country. The reasons are not apparent, as the geared winder is a considerably cheaper proposition than the winder with a slow-speed motor coupled direct to the drum shaft, and double helical gears possess in every instance a safety factor which is probably larger than the safety factor it is customary to reckon with in general engineering practice, due to the fact that considerations of wear call for gear dimensions which lie far beyond what would be required by considerations of strength.

An entirely new field of the application of gearing is the drive of high lift centrifugal pumps. For small and medium powers electric motors can be easily built for the required pump speeds, but for large powers the most efficient high lift pump has generally to run at a speed which can no longer be

Digitized by Google

regarded as normal or desirable for the electric motor. In such cases the use of a standard speed motor with speeding up gear offers the great advantage that a motor of size and speed can be selected which is also in use on other machinery in the mine, so that common spare parts may be kept. The loss in such gears, amounting to not more than 3 to 4 per cent., will hardly be more than the difference in efficiency between a standard motor and a motor of particularly small diameter running at an extreme speed, which necessitates efficient ventilation for cooling purposes.

Electric motor manufacturers used to deprecate direct gear drives for heavy powers, as the number of cases has not been few in which motors have suffered owing to straight cut pinions, mounted direct on the motor shaft. The vibration set up by the gearing and the continuous hammer blows, as tooth after tooth came into engagement, gradually affected the winding, and insulation troubles occurred which could not be accounted for in any other way than by such outside defects. No such trouble has occurred where double helical gearing has been applied, so that the electrical part of the installation has also become more reliable by the introduction of this type of gearing, which, in my opinion, is doubtlessly destined to ultimately oust straight cut gearing for all medium and heavy power drives.

Oerlikon Mine Motors.

A line of motors which have been specially developed for mining work are those made by the Maschinenfabrik Oerlikon.

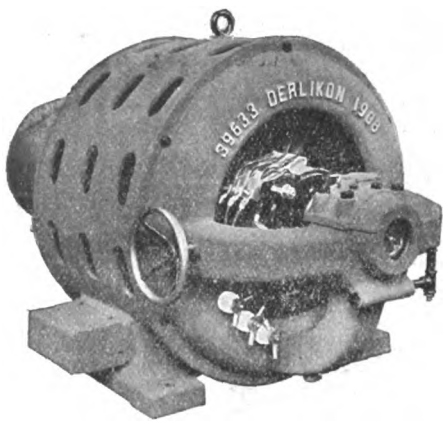

Fig. 1.—Open Type Three-phase Motor with Shield Bearings.

These motors may be divided into two classes—those in which the speed is less than 1,000 revs. per min., and those in which the speed exceeds that amount. The former class include a number of small motors fitted with slip-rings, whose outputs are in general less than 300 H.P. They have from 6 to 16 poles, or in cases where the frequency does not exceed 25, four poles. These motors are usually fitted with end plates, though in the case of those of heavy outputs or with a large number of poles, separate bearing blocks are provided.

A view of one of these motors is shown in Fig. 1. The end plate has a sufficiently large projection which covers up both the slip-rings and the brushes. The end shields can easily be turned through either 90 or 180 deg., so that the motor can be fixed to a vertical wall or on the ceiling if required. In the large size motors the casing is fixed on to the bed plate which carries the bearings.

The bearings are fitted with ring lubrication and can easily be examined by removal of a small plate. The iron of the stator is made up of single sheets which are insulated from one another by paper. The single sheets are held together by two rings which are tightened up by insulated bolts. In order that the cooling may be sufficient, special air channels are provided. The stator winding consists of coils which are suitably insulated according to the voltage and are placed in half-closed slots. Where the voltage exceeds 4,000 the coils themselves are insulated from the iron by means of shellac, or some other similar material. Where the bearings are not carried on the end plates a specially protected ring is provided to prevent the windings being damaged from outside. The rings are sufficiently wide to cover the rotor winding as well. In this class of motor the rotor is generally provided with slip-rings whatever the size of the motor may be. The motors are provided with arrangements for short-circuiting the rotor and for raising the brushes. To short-circuit the motor a sleeve carrying contact fingers is pushed under the slip rings and the arrangement for lifting the bushes is designed so that the brushes are raised as soon as the rotor is short-circuited. This arrangement is

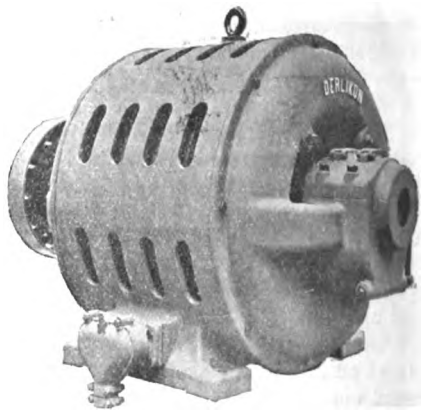

Fig. 2.—Type "A" Three-phase Motor, 2,000 Volts 1,450 Revs. per Min.

worked in the case of motors with the end plates by means of the hand wheel, and in the case of motors with separate bearings by means of a lever. This class of motor can either be provided with separate starters or with starters connected direct to the motor. In the latter case the starters are interlocked with the short-circuiting and the brush lifting equipment, so that cutting out the resistance, short-circuiting the rotor, and lifting the brushes both at starting and stopping can be effected by means of turning one hand wheel progressively in one or the other direction. It is, therefore, claimed to be quite impossible for the motor to be damaged through any mistake in the order of operations being made.

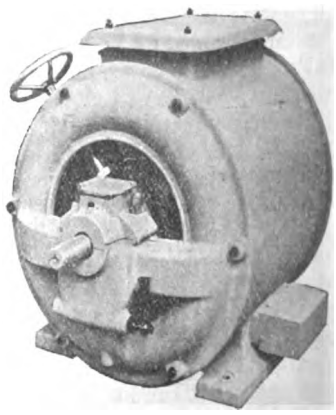

Fig. 3.—Three-phase Ventilated Motor, 100 H.P., 500 Volts 1,450 Revs per Min.

An example of the second class of motors is shown in Fig. 2. These motors have been specially designed for the driving of high-speed pumps and ventilators. These are relatively small in size, and are fitted with hand wheels and short-circuiting rotor, the speed varying between 1,450 and 3,000 revs. per min. In particular cases, however, slip-rings can be provided. Fig. 3 shows another motor of this class of the ventilated enclosed type. This motor, has a capacity of 100 H.P. and is fitted with slip-ring. Mr. G. Wuthrich, Oswaldestre House Norfolk-street, W.C., is the representative of Maschinenfabrik Oerlikon in this country.

H.M. DOCKYARD, CHATHAM.—By order of the Lords Commissioners of the Admiralty.—Messrs.

FULLER, HORSEY, SONS & CASSELL will include in their SALE by AUCTION, at H.M. DOCKYARD, CHATHAM, on TUESDAY, May 9th, and following days, at Eleven o'clock precisely each day, 210 tons Scrap Brass and Mixed Metal; 27 tons White Metal; 28 tons Manganese and Phosphor Bronze; 800 tons Mild Scrap Steel; 580 tons Wrought and Cast Iron Scrap; 20 tons Old Steel Tools; 100 tons Steel Wire Rope; 22 tons Foundry Ashes; 76 tons Lead and Zinc Ashes and Bottoms; 30 tons Electric Cable, Electrical Gear and Stores various; 20 Old Ships' and Boats' Boilers; 26 Forges; 2 Dynamos; 12 Old Engines; Pumps; Machine Tools, including 15 Lathes, 20 Slotting, Punching, Shearing, Drilling, &c., Machines; 3 Steam Launches; Lamps and Lanterns; Iron and Wood Blocks; Hydraulic Jacks; Shovels; and numerous other effects.

May be viewed three days prior to and on mornings of Sale, during Dockyard Working Hours only, and Catalogues (6d. each), had at the Dockyard, or of Messrs. FULLER, HORSEY, SONS & CASSELL, 11, Billiter-square, London, E.C.

MISCELLANEOUS PLANT, &c., FOR SALE.

HIGH-CLASS ELECTRIC PLANT.

TRIPLE EXPANSION VERTICAL ENGINE,

1,125/1,300 I.H.P. 160 lbs. pressure, coupled direct to Continuous-Current **GENERATOR**, 3,000 amp. 220/280 volts, or 440/560 volts, for tramway work. Only run 2,994 hours. Splendid plant. Cost £5,000. **Price £1,950**

Apply ELEKTRON LIM. in Liq., Gothenburg.

CHEAP ELECTRIC PLANT—4 vertical TRIPLE EXPANSION ENGINES, 250/300 I.H.P., 150 lbs. pressure, rope driving, in good condition, each arranged to drive two continuous-current Dynamos, each 640 amp. 110/140 volt or 220/240 volt. With central condenser. Price for the lot £1,150. Each engine or dynamo, if desired, will be sold separately.—Apply ELEKTRON LIM. in Liq., Gothenburg.

8 FIRST-CLASS DYNAMOS, each 640 amp. 110 volts, Crompton armatures, in good condition. Price each £85.—Apply ELEKTRON LIM. in Liq., Gothenburg.

FOR SALE.—Complete numbers of the "SOCIETY OF TELEGRAPH ENGINEERS JOURNAL" from the formation of the Society in 1872 till the year 1896; the first 10 years bound half calf, all in perfect condition.—For particulars apply to Mrs. ADAMSON, 58, London-road, Reading.

APPOINTMENT VACANT.

THE ELECTRICAL POWER STORAGE CO., Ltd., require the services of a qualified

SALES MANAGER.

Applicants must have up-to-date experience of Storage Batteries and possess a good connection.

Applications will only be considered from those who have held a similar position, and preference will be given to a man experienced in framing publications and advertisements.

A liberal salary will be offered to a competent man.—Applications, which will be treated in strict confidence, stating full particulars of past and present employment, age, &c., to be addressed to the SECRETARY of the Company, 4, Great Winchester-street, London, E.C.

SITUATIONS, &c., VACANT

WANTED, for North of England Biscuit Factory, ELECTRICIAN for charge of installation and control of three assistants. The installation consists of own generators, motors, continuous current, arcs and incandescents. Must be conversant with three-wire system and have held similar post.—Copies only of testimonials and full previous experience together with wage required.—E. H. W., ELECTRICIAN Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London.

WANTED, immediately, for the Mining Dept. of a large Continental Electrical Works, a young ELECTRICAL ENGINEER (one having a working knowledge of German preferred) for a junior position, with good future prospects. Applicants must have had a thorough College and shop training, together with some knowledge of the requirements of Collieries and Iron and Steel Works as far as electrical driving is concerned.—Apply, giving full particulars of previous training and experience, and stating age, and salary in last position, to Box E. K. C., ELECTRICIAN Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London.

JUNIOR SHIFT ENGINEER wanted to take charge, on an eight-hour shift of steam generating D.C. plant and three-phase A.C. converting machinery. Must have had previous similar experience. Salary to commence 35/- per week. Will be required to live within the Borough of Stepney.—Applications, stating age, experience and accompanied by not more than three recent testimonials, to be addressed to the ENGINEER AND MANAGER, 27, Osborn Street, Whitechapel, London, E.

ONE OR TWO DRAUGHTSMEN wanted by large electrical firm.—Apply stating age, experience and salary required, to E. K. A., ELECTRICIAN Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London.

WANTED.—Thoroughly reliable ESTIMATOR in leading firm of Manufacturing Electrical Engineers in Midlands.—State age, experience and salary required, to Box No. 239, at Horncastle's, 61, Cheapside, London, E.C.

CONSULTING ENGINEER (Radiotelegraphy), has Vacancy for PUPIL ASSISTANT. No premium. Small salary.—Apply E.H. X., ELECTRICIAN Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London.

EDUCATIONAL NOTICES.

TO PARENTS AND GUARDIANS.—VACANCIES for YOUNG GENTLEMEN, aged 17 to 24, for WIRELESS TELEGRAPH and CABLE SERVICES. Lucrative positions when proficient. Small premium. Board and residence if desired. 109 appointments obtained by our students during the past year. Recognised by authorities as best equipped and most successful school in the Kingdom (owns two Wireless Telegraph Stations licensed by Government).—Apply BRITISH SCHOOL OF TELEGRAPHY (LTD.), 179, Clapham-road, London, S.W.

RADIO OR WIRELESS TELEGRAPHY.—Good positions can be obtained in this branch of the Telegraph Service by men (18 to 25) having electrical knowledge (and willing to go to sea) after a comparatively short period of tuition at the LONDON TELEGRAPH TRAINING COLLEGE (LTD.). This Institution (established 18 years) possesses TWO WIRELESS TELEGRAPH STATIONS equipped with complete Marconi Installations of the latest type. Commencing remuneration from about £100 a year. The demand for some time past for competent men has exceeded the supply.—Write for Prospectus to SECRETARY (D) Morse House, Earl's Court, London, S.W.
